Status:

This document was last revised or approved by the Key Management Interoperability Protocol TC on the above date. The level of approval is also listed above. Check the "Latest Version" or "Latest Approved Version" location noted above for possible later revisions of this document.

Technical Committee members should send comments on this specification to the Technical Committee's email list. Others should send comments to the Technical Committee by using the "Send A Comment" button on the Technical Committee's web page at <http://www.oasis-open.org/committees/kmip/>.

For information on whether any patents have been disclosed that may be essential to implementing this specification, and any offers of patent licensing terms, please refer to the Intellectual Property Rights section of the Technical Committee web page (<http://www.oasis-open.org/committees/kmip/ipr.php>.)

The non-normative errata page for this specification is located at <http://www.oasis-open.org/committees/kmip/>.

Notices

Copyright © OASIS® ~~2010~~2009. All Rights Reserved.

All capitalized terms in the following text have the meanings assigned to them in the OASIS Intellectual Property Rights Policy (the "OASIS IPR Policy"). The full Policy may be found at the OASIS website.

This document and translations of it may be copied and furnished to others, and derivative works that comment on or otherwise explain it or assist in its implementation may be prepared, copied, published, and distributed, in whole or in part, without restriction of any kind, provided that the above copyright notice and this section are included on all such copies and derivative works. However, this document itself may not be modified in any way, including by removing the copyright notice or references to OASIS, except as needed for the purpose of developing any document or deliverable produced by an OASIS Technical Committee (in which case the rules applicable to copyrights, as set forth in the OASIS IPR Policy, must be followed) or as required to translate it into languages other than English.

The limited permissions granted above are perpetual and will not be revoked by OASIS or its successors or assigns.

This document and the information contained herein is provided on an "AS IS" basis and OASIS DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO ANY WARRANTY THAT THE USE OF THE INFORMATION HEREIN WILL NOT INFRINGE ANY OWNERSHIP RIGHTS OR ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE.

OASIS requests that any OASIS Party or any other party that believes it has patent claims that would necessarily be infringed by implementations of this OASIS Committee Specification or OASIS Standard, to notify OASIS TC Administrator and provide an indication of its willingness to grant patent licenses to such patent claims in a manner consistent with the IPR Mode of the OASIS Technical Committee that produced this specification.

OASIS invites any party to contact the OASIS TC Administrator if it is aware of a claim of ownership of any patent claims that would necessarily be infringed by implementations of this specification by a patent holder that is not willing to provide a license to such patent claims in a manner consistent with the IPR Mode of the OASIS Technical Committee that produced this specification. OASIS may include such claims on its website, but disclaims any obligation to do so.

OASIS takes no position regarding the validity or scope of any intellectual property or other rights that might be claimed to pertain to the implementation or use of the technology described in this document or the extent to which any license under such rights might or might not be available; neither does it represent that it has made any effort to identify any such rights. Information on OASIS' procedures with respect to rights in any document or deliverable produced by an OASIS Technical Committee can be found on the OASIS website. Copies of claims of rights made available for publication and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementers or users of this OASIS Committee Specification or OASIS Standard, can be obtained from the OASIS TC Administrator. OASIS makes no representation that any information or list of intellectual property rights will at any time be complete, or that any claims in such list are, in fact, Essential Claims.

The names "OASIS", "KMIP" are trademarks of OASIS, the owner and developer of this specification, and should be used only to refer to the organization and its official outputs. OASIS welcomes reference to, and implementation and use of, specifications, while reserving the right to enforce its marks against misleading uses. Please see <http://www.oasis-open.org/who/trademark.php> for above guidance.

1 Introduction

This Key Management Interoperability Protocol Usage Guide is intended to complement the Key Management Interoperability Protocol Specification [KMIP-Spec] by providing guidance on how to implement the Key Management Interoperability Protocol (KMIP) most effectively to ensure interoperability. In particular, it includes the following guidance:

- Clarification of assumptions and requirements that drive or influence the design of KMIP and the implementation of KMIP-compliant key management.
- Specific recommendations for implementation of particular KMIP functionality.
- Clarification of mandatory and optional capabilities for conformant implementations.
- Functionality considered for inclusion in KMIP V1.0, but deferred to subsequent versions of the standard.

A selected set of conformance profiles and authentication suites are defined in the KMIP Profiles specification [KMIP-Prof].

Further assistance for implementing KMIP is provided by the KMIP Use Cases for Proof of Concept Testing document [KMIP-UC] that describes a set of recommended test cases and provides the TTLV (Tag/Type/Length/Value) format for the message exchanges defined by those use cases.

1.1 Terminology

For a list of terminologies refer to [KMIP-Spec].

158 2 Assumptions

159 The section describes assumptions that underlie the KMIP protocol and the implementation of clients and
160 servers that utilize the protocol.

161 2.1 Island of Trust

162 Clients may be provided key material by the server, but they only use that keying material for the
163 purposes explicitly listed in the delivery payload. Clients that ignore these instructions and use the keys in
164 ways not explicitly allowed by the server are non-compliant. There is no requirement for the key
165 management system, however, to enforce this behavior.

166 2.2 Message Security

167 KMIP relies on the chosen authentication suite as specified in [\[KMIP-Prof\]](#) to authenticate the client and
168 on the underlying transport protocol to provide confidentiality, integrity, message authentication and
169 protection against replay attack. KMIP offers a wrapping mechanism for the Key Value that does not rely
170 on the transport mechanism used for the messages; the wrapping mechanism is intended for importing or
171 exporting managed cryptographic objects.

172 2.3 State-less Server

173 The protocol operates on the assumption that the server is state-less, which means that there is no
174 concept of “sessions” inherent in the protocol. State-less server operation is much more reliable and
175 easier to implement than stateful operation, and is consistent with possible implementation scenarios,
176 such as web-services-based servers. This does not mean that the server itself maintains no state, only
177 that the protocol does not require this.

178 2.4 Extensible Protocol

179 The protocol provides for “private” or vendor-specific extensions, which allow for differentiation among
180 vendor implementations. However, any objects, attributes and operations included in an implementation
181 are always implemented as specified in [\[KMIP-Spec\]](#), regardless of whether they are optional or
182 mandatory.

183 2.5 Server Policy

184 [A server is required to be conformant to KMIP and support the conformance clauses as specified in](#)
185 [\[KMIP-Spec\]. However, a server may refuse a server-supported operation or client-settable attribute if](#)
186 [disallowed by the server policy.](#)

187 2.5.2.6 Support for Cryptographic Objects

188 The protocol supports all reasonable key management system-related cryptographic objects. This list
189 currently includes:

- 190 • Symmetric Keys
- 191 • Split (multi-part) Keys
- 192 • Asymmetric Key Pairs and their components
- 193 • Digital Certificates
- 194 • Derived Keys
- 195 • Secret Data
- 196 • Opaque (non-interpretable) cryptographic objects

197 **2.62.7 Client-Server Message-based Model**

198 The protocol operates primarily in a client-server, message-based model. This means that most protocol
199 exchanges are initiated by a client sending a request message to a server, which then sends a response
200 to the client. The protocol also provides optional mechanisms to allow for unsolicited notification of events
201 to clients using the Notify operation, and unsolicited delivery of cryptographic objects to clients using the
202 Put operation; that is, the protocol allows a “push” model, whereby the server initiates the protocol
203 exchange with either a Notify or Put operation. These Notify or Put features are optionally supported by
204 servers and clients. Clients may register in order to receive such events/notifications. Registration is
205 implementation-specific and not described in the specification.

206 **2.72.8 Synchronous and Asynchronous Messages**

207 The protocol allows two modes of operation. Synchronous (mandatory) operations are those in which a
208 client sends a request and waits for a response from the server. Polled Asynchronous operations
209 (optional) are those in which the client sends a request, the server responds with a “pending” status, and
210 the client polls the server for the completed response and completion status. Server implementations may
211 choose not to support the Polled Asynchronous feature of the protocol.

212 **2.82.9 Support for “Intelligent Clients” and “Key Using Devices”**

213 The protocol supports intelligent clients, such as end-user workstations, which are capable of requesting
214 all of the functions of KMIP. It also allows subsets of the protocol and possible alternate message
215 representations in order to support less-capable devices, which only need a subset of the features of
216 KMIP.

217 **2.92.10 Batched Requests and Responses**

218 The protocol contains a mechanism for sending batched requests and receiving the corresponding
219 batched responses, to allow for higher throughput on operations that deal with a large number of entities,
220 e. g., requesting dozens or hundreds of keys from a server at one time, and performing operations in a
221 group. An option is provided to indicate whether to continue processing requests after an earlier request
222 in the batch fails or to stop processing the remaining requests in the batch. Note that there is no option to
223 treat an entire batch as atomic, that is, if a request in the batch fails, then preceding requests in the batch
224 are not undone or rolled back (see Section 3.15). A special ID Placeholder (see Section 3.19) is provided
225 in KMIP to allow related requests in a batch to be pipelined.

226 **2.102.11 Reliable Message Delivery**

227 The reliable message delivery function is relegated to the transport protocol, and is not part of the key
228 management protocol itself.

229 **2.112.12 Large Responses**

230 For requests that could result in large responses, a mechanism in the protocol allows a client to specify in
231 a request the maximum allowed size of a response. The server indicates in a response to such a request
232 that the response would have been too large and, therefore, is not returned.

233 **2.122.13 Key Life-cycle and Key State**

234 **[KMIP-Spec]** describes the key life-cycle model, based on the NIST SP 800-57 key state definitions
235 **[SP800-57-1]**, supported by the KMIP protocol. Particular implications of the key life-cycle model in terms
236 of defining time-related attributes of objects are discussed in Section 3.5 below.

237

238 3 Usage Guidelines

239 This section provides guidance on using the functionality described in the Key Management
240 Interoperability Protocol Specification.

241 3.1 Authentication

242 As discussed in [\[KMIP-Spec\]](#), a conforming KMIP implementation establishes and maintains channel
243 confidentiality and integrity, and ~~provides assurance of~~ [proves](#) server authenticity for KMIP messaging.
244 Client authentication is performed according to the chosen KMIP authentication suite as specified in
245 [\[KMIP-Prof\]](#). Other mechanisms for client and server authentication are possible and optional for KMIP
246 implementations.

247 KMIP implementations that [support the KMIP-defined Credential Types](#) or use other vendor-specific
248 mechanisms for authentication may use the [optional Authentication field specified inside the Request](#)
249 [HeaderCredential-attribute](#) to include additional identification information. Depending on the server's
250 configuration, the server may interpret the identity of the requestor from the Credential object, [contained](#)
251 [in the Authentication structure](#) if it is not provided during the channel-level authentication. For example, in
252 addition to performing mutual authentication during a [SSL/TLS handshake](#), the client passes the
253 Credential object (e.g., a username and password) in the request. If the requestor's username is not
254 specified inside the client certificate and is instead specified in the Credential object, the server interprets
255 the identity of the requestor from the Credential object. This supports use cases where channel-level
256 authentication authenticates a machine or service that is used by multiple users of the KMIP server. If the
257 client provides the username of the requestor in both the client certificate and the Credential object, the
258 server verifies that the usernames are the same. If they differ, the authentication fails and the server
259 returns an error. If no Credential object is included in the request, the username of the requestor is
260 expected to be provided inside the certificate. [If no username is provided in the client certificate and no](#)
261 [Credential object is included in the request message, the server is expected to refuse authentication and](#)
262 [return an error.](#)

263 If authentication is unsuccessful, and it is possible to return an "authentication not successful" error, this
264 error should be returned in preference to any other result status. This prevents status code probing by a
265 client that is not able to authenticate.

266 Server decisions regarding which operations to reject if there is insufficiently strong authentication of the
267 client are not specified in the protocol. However, see Section 3.2 for operations for which authentication
268 and authorization are particularly important.

269 3.1.1 Credential

270 [\[KMIP-Spec\]](#) defines the Username and Password structure for the Credential Type Username and
271 Password. The structure consists of two fields: Username and Password. Password is a recommended,
272 but optional, field, which may be excluded only if the client is authenticated using one of the
273 authentication suites defined in [\[KMIP-Prof\]](#). For example, if the client performs client certificate
274 authentication during the TLS handshake, and the Authentication field is provided in the Message
275 Request, the Password field is an optional field in the Username and Password structure of the Credential
276 object.

277
278 [The Credential object is used to provide additional identification information. As described above, for](#)
279 [certain use cases, channel-level authentication may only authenticate a machine or service that is used](#)
280 [by multiple clients of the KMIP server. The Credential object may be used in this scenario to identify](#)
281 [individual clients by specifying the username in the Username and Password structure. Depending on the](#)
282 [client's environment, the username may be the device's serial number, the volume name or some other](#)
283 [unique identifier.](#)

Formatted: Font:

284 [Multiple clients should not be authenticated using the same channel-level authentication credential \(e.g.,](#)
285 [the same client certificate\). The Credential object may be used to authenticate individual clients by](#)
286 [requiring the Username and Password to be provided in the Credential object.](#)

287 **3.2 Authorization for Revoke, Recover, Destroy and Archive** 288 **Operations**

289 Neither authentication nor authorization is handled by the KMIP protocol directly. In particular, the
290 Credential attribute is not guaranteed to be an authenticated identity of the requesting client. However,
291 the authentication suite, as specified in [\[KMIP-Prof\]](#), describes how the client identity is established for
292 KMIP-compliant implementations. This authentication is performed for all KMIP operations, with the single
293 exception of the Query operation.

294 Certain operations that may be requested by a client via KMIP, particularly Revoke, Recover, Destroy and
295 Archive, may have a significant impact on the availability of a key, on server performance and on key
296 security. When a server receives a request for one of these operations, it should ensure that the client
297 has authenticated its identity (see the Authentication Suites section in [\[KMIP-Prof\]](#)). The server should
298 also ensure that the client requesting the operation is an object creator, security officer or other identity
299 authorized to issue the request. It may also require additional authentication to ensure that the object
300 owner or a security officer has issued that request. Even with such authentication and authorization,
301 requests for these operations should be considered only a "hint" to the key management system, which
302 may or may not choose to act upon this request.

303 **3.3 Using Notify and Put Operations**

304 The Notify and Put operations are the only operations in the KMIP protocol that are initiated by the server,
305 rather than the client. As client-initiated requests are able to perform these functions (e.g., by polling to
306 request notification), these operations are optional for conforming KMIP implementations. However, they
307 provide a mechanism for optimized communication between KMIP servers and clients and have,
308 therefore, been included in [\[KMIP-Spec\]](#).

309 In using Notify and Put, the following constraints and guidelines should be observed:

- 310 • The client registers with the server, so that the server knows how to locate the client to which a
311 Notify or Put is being sent and which events for the Notify are supported. However, such
312 registration is outside the scope of the KMIP protocol. Registration also includes a specification of
313 whether a given client supports Put and Notify, and what attributes may be included in a Put for a
314 particular client.
- 315 • Communication between the client and the server is properly authenticated to forestall man-in-
316 the-middle attacks in which the client receives Notify or Put operations from an unauthenticated
317 server. Authentication for a particular client/server implementation is at a minimum accomplished
318 using one of the mandatory authentication mechanisms (see [\[KMIP-Prof\]](#)). Further strengthening
319 of the client/server communications integrity by means of signed message content and/or
320 wrapped keys is recommended. Attribute values other than "Last Change Date" should not be
321 included in a Notify to minimize risk of exposure of attribute information.
- 322 • In order to minimize possible divergence of key or state information between client and server as
323 a result of server-initiated communication, any client receiving Notify or Put messages returns
324 acknowledgements of these messages to the server. This acknowledgement may be at
325 communication layers below the KMIP layer, such as by using transport-level acknowledgement
326 provided in TCP/IP.
- 327 • For client devices that are incapable of responding to messages from the server, communication
328 with the server happens via a proxy entity that communicates with the server, using KMIP, on
329 behalf of the client. It is possible to secure communication between a proxy entity and the client
330 using other, potentially proprietary mechanisms.

3.4 Usage Allocation

Usage should be allocated and handled carefully at the client, since power outages or other types of client failures (crashes) may render allocated usage lost. For example, in the case of a key being used for the encryption of tapes, such a loss of the usage allocation information following a client failure during encryption may result in the necessity for the entire tape backup session to be re-encrypted using a different key, if the server is not able to allocate more usage. It is possible to address this through such approaches as caching usage allocation information on stable storage at the client, and/or having conservative allocation policies at the server (e.g., by keeping the maximum possible usage allocation per client request moderate). In general, usage allocations should be as small as possible; it is preferable to use multiple smaller allocation requests rather than a single larger request to minimize the likelihood of unused allocation.

3.5 Key State and Times

[KMIP-Spec] provides a number of time-related attributes, including the following:

- Initial Date: The date and time when the managed cryptographic object was first created by or registered at the server
- Activation Date: The date and time when the managed cryptographic object may begin to be used for applying cryptographic protection to data
- Process Start Date: The date and time when a managed symmetric key object may begin to be used for processing cryptographically protected data
- Protect Stop Date: The date and time when a managed symmetric key object may no longer be used for applying cryptographic protection to data
- Deactivation Date: The date and time when the managed cryptographic object may no longer be used for any purpose, except for decryption, signature verification, or unwrapping, but only under extraordinary circumstances and when special permission is granted
- Destroy Date: The date and time when the managed cryptographic object was destroyed
- Compromise Occurrence Date: The date and time when the managed cryptographic object was first believed to be compromised
- Compromise Date: The date and time when the managed cryptographic object is entered into the compromised state
- Archive Date: The date and time when the managed object was placed in Off-Line storage

These attributes apply to all cryptographic objects (symmetric keys, asymmetric keys, etc) with exceptions as noted in [KMIP-Spec]. However, certain of these attributes (such as the Initial Date) are not specified by the client and are implicitly set by the server.

In using these attributes, the following guidelines should be observed:

- As discussed for each of these attributes in Section 3 of [KMIP-Spec], a number of these times are set once and it is not possible for the client or server to modify them. However, several of the time attributes (particularly the Activation Date, Protect Start Date, Process Stop Date and Deactivation Date) may be set by the server and/or requested by the client. Coordination of time-related attributes between client and server, therefore, is primarily the responsibility of the server, as it manages the cryptographic object and its state. However, special conditions related to time-related attributes, governing when the server accepts client modifications to time-related attributes, may be negotiated by policy exchange between the client and server, outside the Key Management Interoperability Protocol.

In general, state transitions occur as a result of operational requests, such as Create, Create Key Pair, Register, Activate, Revoke, and Destroy. However, clients may need to specify times in the future for such things as Activation Date, Deactivation Date, Process Start Date, and Protect Stop Date.

380 KMIP allows clients to specify times in the past for such attributes as Activation Date and
381 Deactivation Date. This is intended primarily for clients that were disconnected from the server at
382 the time that the client performed that operation on a given key.

- 383 • It is valid to have a projected Deactivation Date when there is no Activation Date. This means,
384 however, that the key is not yet active, even though its projected Deactivation Date has been
385 specified. A valid Deactivation Date is greater than or equal to the Activation Date.
- 386 • The Protect Stop Date may be equal to, but may not be later than the Deactivation Date.
387 Similarly, the Process Start Date may be equal to, but may not precede, the Activation Date.
388 KMIP implementations should consider specifying both these attributes, particularly for symmetric
389 keys, as a key may be needed for processing protected data (e.g., decryption) long after it is no
390 longer appropriate to use it for applying cryptographic protection to data (e.g., encryption).

391 • KMIP does not allow an Active object to be destroyed with the Destroy operation. The server is
392 required to return an error, if the client invokes the Destroy operation on an Active object. To
393 destroy an Active object, clients are required to first call the Revoke operation or explicitly set the
394 Deactivation Date of the object. Once the object is in Deactivated state, clients may destroy the
395 object by calling the Destroy operation. These operations may be performed in a batch. If other
396 time-related attributes (e.g., Protect Stop Date) are set to a future date, the server should set
397 these to the Deactivation Date.

398 • ~~If a Destroy operation is performed, resulting in the Destroy Date being set, and the object has~~
399 ~~not already been deactivated, the deactivation of the object is also performed prior to the Destroy~~
400 ~~operation, so that Destroy Date is greater than or equal to the Deactivation Date. If other time-~~
401 ~~related attributes (e.g., Protect Stop Date) are set to a future date, the server should set these to~~
402 ~~the deactivation date.~~

- 403 • After a cryptographic object is destroyed, a key management server may retain certain
404 information about the object, such as the Unique Identifier.

405 KMIP allows the specification of attributes on a per-client basis, such that a server could maintain or
406 present different sets of attributes for different clients. This flexibility may be necessary in some cases,
407 such as when a server maintains the availability of a given key for some clients, even after that same key
408 is moved to an inactive state (e.g., ~~Deactivated~~-deactivated state) for other clients. However, such an
409 approach might result in significant inconsistencies regarding the object state from the point of view of all
410 participating clients and should, therefore, be avoided. A server should maintain a consistent state for
411 each object, across all clients that have or are able to request that object.

412 3.6 Template

413 The usage of templates is an alternative approach for setting attributes in an operation request. Instead of
414 individually specifying each attribute, a template may be used to set any of the following attributes for a
415 managed object:

- 416 • Cryptographic Algorithm
- 417 • Cryptographic Length
- 418 • Cryptographic Domain Parameters
- 419 • Cryptographic Parameters
- 420 • Operation Policy Name
- 421 • Cryptographic Usage Mask
- 422 • Usage Limits
- 423 • Activation Date
- 424 • Process Start Date
- 425 • Protect Stop Date
- 426 • Deactivation Date
- 427 • Object Group

- 428 • [Application Specific Information](#)
- 429 • [Contact Information](#)
- 430 • [Custom Attribute](#)

431 [In addition to these attributes, the template has attributes that are applicable to the template itself. These](#)
432 [include the attributes \(Unique Identifier, Initial Date, Last Change Date, and Archive Date\) set implicitly](#)
433 [after successfully completing a certain operation and attributes set by the client \(Object Type and Name\)](#)
434 [in the Register request. When registering a template, the Name attribute for the template should be set. It](#)
435 [is used to specify and identify the template in the Template-Attribute structure when attributes for a](#)
436 [managed object are set.](#)

437
438 [The Template-Attribute structure allows for multiple template names and individual attributes to be](#)
439 [specified in an operation request. The structure is used in the Create, Create Key Pair, Register, Re-key,](#)
440 [Derive Key, Certify, and Re-certify operations. All of these operations with the exception of the Create](#)
441 [Key Pair operation use the Template-Attribute tag. The Create Key Pair operation uses the Common](#)
442 [Template-Attribute, Private Key Template Attribute, and Public Key Template-Attribute tags.](#)

443
444 [Templates may be the subject of the Register, Locate, Get, Get Attributes, Get Attribute List, Add](#)
445 [Attribute, Modify Attribute, Delete Attribute, Delete Attribute, and Destroy operations. Clients are not able](#)
446 [to create a template with the Create operation; instead templates are created using the Register](#)
447 [operation. When the template is the subject of the operation, the Unique ID is used to identify the](#)
448 [template. The template name is only used to identify the template inside a Template-Attribute structure.](#)

449 [3.6.1 Template Usage Examples](#)

450 [The purpose of these examples is to illustrate how templates are used. The first example shows how a](#)
451 [template is registered. The second example shows how the newly registered template is used to create a](#)
452 [symmetric key.](#)

453 [3.6.1.1 Example of Registering a Template](#)

454 [In this example, a client registers a template by encapsulating attributes for creating a 256-bit AES key](#)
455 [with the Cryptographic Usage Mask set to Encrypt and Decrypt.](#)

456 [The following is specified inside the Register Request Payload:](#)

- 457 • [Object Type: Template](#)
- 458 • [Template-Attribute:](#)
 - 459 - [Name: Template1](#)
 - 460 - [Cryptographic Algorithm: AES](#)
 - 461 - [Cryptographic Length: 256](#)
 - 462 - [Cryptographic Usage Mask: Encrypt and Decrypt](#)
 - 463 - [Operation Policy Name: OperationPolicy1](#)

464
465 [The Operation Policy OperationPolicy1 applies to the AES key being created using the template. It is not](#)
466 [used to control operations on the template itself. KMIP does not allow operation policies to be specified](#)
467 [for controlling operations on the template itself. The default policy for template objects is used for this](#)
468 [purpose and is specified in the KMIP Specification.](#)

469 [3.6.1.2 Example of Creating a Symmetric Key using a Template](#)

470 [In this example, the client uses the template created in example 3.6.1 to create a 256-bit AES key.](#)

471
472 [The following is specified in the Create Request Payload:](#)

- 473
- 474 • Object Type: Symmetric Key
- 475 • Template-Attribute:
- 476 - Name: Template1
- 477 - Attribute:
- 478 Name: AESkey
- 479 Custom Attribute: x-ID74592
- 480

481 The Template-Attribute specifies both a template name and additional attributes. The Name attribute is
482 not an attribute that may be set by a template. The Name attribute set for the template applies to the
483 template itself (e.g., Template1 is the Name attribute of the Template object). The Name attribute for the
484 symmetric key is therefore specified separately under Attribute. It is possible to specify the Custom
485 Attribute inside the template; however, this particular example sets this attribute separately.

486 It is possible for a server to maintain different policy templates for different clients. As in the state
487 transitions described above, however, this practice is discouraged.

488 **3.7 Archive Operations**

489 When the Archive operation is performed, it is recommended that an object identifier and a minimal set of
490 attributes be retained within the server for operational efficiency. In such a case, the retained attributes
491 may include Unique Identifier and State.

492 **3.8 Message Extensions**

493 Any number of vendor-specific extensions may be included in the Message Extension optional structure.
494 This allows KMIP implementations to create multiple extensions to the protocol.

495 **3.9 Unique Identifiers**

496 For clients that require unique identifiers in a special form, out-of-band registration/configuration may be
497 used to communicate this requirement to the server.

498 **3.10 Result Message Text**

499 KMIP specifies the Result Status, the Result Reason and the Result Message as normative message
500 contents. For the Result Status and Result Reason, the enumerations provided in [\[KMIP-Spec\]](#) are the
501 normative values. The values for the Result Message text, on the other hand, are implementation-
502 specific. In consideration of internationalization, it is recommended that any vendor implementation of
503 KMIP provide appropriate language support for the Return Message. How a client specifies the language
504 for Result Messages is outside the scope of the KMIP.

505 **3.11 Query**

506 Query does not explicitly support client requests to determine what operations require authentication. To
507 determine whether an operation requires authentication, a client should request that operation.

508 **3.12 Canceling Asynchronous Operations**

509 If an asynchronous operation is cancelled by the client, no information is returned by the server in the
510 result code regarding any operations that may have been partially completed. Identification and
511 remediation of partially completed operations is the responsibility of the server.

512 It is the responsibility of the server to determine when to discard the status of asynchronous operations.
513 The determination of how long a server should retain the status of an asynchronous operation is
514 implementation-dependent and not defined by KMIP.
515 Once a client has received the status on an asynchronous operation other than “pending”, any
516 subsequent request for status of that operation may return either the same status as in a previous polling
517 request or an “unavailable” response.

518 **3.13 Multi-instance Hash**

519 The Digest attribute contains the output of hashing a managed object, such as a key or a certificate. The
520 server always generates the SHA-256 hash value when the object is created or generated. KMIP allows
521 multiple instances of the digest attribute to be associated with the same managed object. For example, it
522 is common practice for publicly trusted CAs to publish two digests (often referred to as the fingerprint or
523 the thumbprint) of their certificate: one calculated using the SHA-1 algorithm and another using the MD-5
524 algorithm. In this case, each digest would be calculated by the server using a different hash algorithm.

525 **3.14 Returning Related Objects**

526 The key block is intended to return a single object, with associated attributes and other data. For those
527 cases in which multiple related objects are needed by a client, such as the private key and the related
528 certificate specified by RACF and JKS, the client should issue multiple Get requests to obtain these
529 related objects.

530 **3.15 Reducing Multiple Requests through the Use of Batch**

531 KMIP supports batch operations in order to reduce the number of calls between the client and server for
532 related operations. For example, Locate and Get are likely to be commonly accomplished within a single
533 batch request.

534 KMIP does not ensure that batch operations are atomic on the server side. If servers implement such
535 atomicity, the client is able to use the optional “undo” mode to request roll-back for batch operations
536 implemented as atomic transactions. However, support for “undo” mode is optional in the protocol, and
537 there is no guarantee that a server that supports “undo” mode has effectively implemented atomic
538 batches. The use of “undo”, therefore, should be restricted to those cases in which it is possible to assure
539 the client, through mechanisms outside of KMIP, of the server effectively supporting atomicity for batch
540 operations.

541 **3.16 Maximum Message Size**

542 When a server is processing requests in a batch, it should compare the cumulative response size of the
543 message to be returned after each request with the specified Maximum Response Size. If the message is
544 too large, it should prepare a maximum message size error response message at that point, rather than
545 continuing with operations in the batch. This increases the client’s ability to understand what operations
546 have and have not been completed.

547 When processing individual requests within the batch, the server that has encountered a Maximum
548 Response Size error should not return attribute values or other information as part of the error response.

549 **3.17 Using Offset in Re-key and Re-certify Operations**

550 Both the Re-key and the Re-certify operations allow the specification of an offset interval.

551 The Re-key operation allows the client to specify an offset interval for activation of the key. This offset
552 specifies the duration of time between the time the request is made and the time when the activation of
553 the key occurs. If an offset is specified, all other times for the new key are determined from the new
554 Activation Date, based on the intervals used by the previous key, i.e., from the Activation Date to the
555 Process Start Date, Protect Stop Date, etc.

556 The Re-certify operation allows the client to specify an offset interval that indicates the difference between
557 the Initial Date of the new certificate and the Activation Date of the new certificate. As with the Re-key
558 operation, all other times for the certificate are determined using the intervals used for the previous
559 certificate.

560 3.18 Locate Queries

561 It is possible to formulate Locate queries to address any of the following conditions:

- 562 • Exact match of a transition to a given state. Locate the key(s) with a transition to a certain state at
563 a specified time (t).
- 564 • Range match of a transition to a given state. Locate the key(s) with a transition to a certain state
565 at any time at or between two specified times (t and t').
- 566 • Exact match of a state at a specified time. Locate the key(s) that are in a certain state at a
567 specified time (t).
- 568 • Match of a state during an entire time range. Locate the key(s) that are in a certain state during
569 an entire time specified with times (t and t'). Note that the Activation Date could occur at or before
570 t and that the Deactivation Date could occur at or after t'+1.
- 571 • Match of a state at some point during a time range. Locate the key(s) that are in a certain state at
572 some time at or between two specified times (t and t'). In this case, the transition to that state
573 could be before the start of the specified time range.

574 This is accomplished by allowing any date/time attribute to be present either once (for an exact match) or
575 at most twice (for a range match).

576 For instance, if the state we are interested in is Active, the Locate queries would be the following
577 (corresponding to the bulleted list above):

- 578 • Exact match of a transition to a given state: Locate (ActivationDate(t)). Locate keys with an
579 Activation Date of t.
- 580 • Range match of a transition to a given state: Locate (ActivationDate(t), ActivationDate(t')). Locate
581 keys with an Activation Date at or between t and t'.
- 582 • Exact match of a state at a specified time: Locate (ActivationDate(0), ActivationDate(t),
583 DeactivationDate(t+1), DeactivationDate(MAX_INT), CompromiseDate(t+1),
584 CompromiseDate(MAX_INT)). Locate keys in the Active state at time t, by looking for keys with a
585 transition to Active before or until t, and a transition to Deactivated or Compromised after t
586 (because we don't want the keys that have a transition to Deactivated or Compromised before t).
587 The server assumes that keys without a DeactivationDate or CompromiseDate is equivalent to
588 MAX_INT (i.e., infinite).
- 589 • Match of a state during an entire time range: Locate (ActivationDate(0), ActivationDate(t),
590 DeactivationDate(t'+1), DeactivationDate(MAX_INT), CompromiseDate(t'+1),
591 CompromiseDate(MAX_INT)). Locate keys in the Active state during the entire time from t to t'.
- 592 • Match of a state at some point during a time range: Locate (ActivationDate(0), ActivationDate(t'-
593 1), DeactivationDate(t+1), DeactivationDate(MAX_INT), CompromiseDate(t+1),
594 CompromiseDate(MAX_INT)). Locate keys in the Active state at some time from t to t', by looking
595 for keys with a transition to Active between 0 and t'-1 and exit out of Active on or after t+1.

596 The queries would be similar for Initial Date, Deactivation Date, Compromise Date and Destroy Date.

597 In the case of the Destroyed-Compromise state, there are two dates recorded: the Destroy Date and the
598 Compromise Date. For this state, the Locate operation would be expressed as follows:

- 599 • Exact match of a transition to a given state: Locate (CompromiseDate(t), State(Destroyed-
600 Compromised)) and Locate (DestroyDate(t), State(Destroyed-Compromised)). KMIP does not
601 support the OR in the Locate request, so two requests should be issued. Locate keys that were
602 Destroyed and transitioned to the Destroyed-Compromised state at time t, and locate keys that
603 were Compromised and transitioned to the Destroyed-Compromised state at time t.

- 604 • Range match of a transition to a given state: Locate (CompromiseDate(t), CompromiseDate(t'),
605 State(Destroyed-Compromised)) and Locate (DestroyDate(t), DestroyDate(t'), State(Destroyed-
606 Compromised)). Locate keys that are Destroyed-Compromised and were Compromised or
607 Destroyed at or between t and t'.
- 608 • Exact match of a state at a specified time: Locate (CompromiseDate(0), CompromiseDate(t),
609 DestroyDate(0), DestroyDate(t)); nothing else is needed, since there is no exit transition. Locate
610 keys with a Compromise Date at or before t, and with a Destroy Date at or before t. These keys
611 are, therefore, in the Destroyed-Compromised state at time t.
- 612 • Match of a state during an entire time range: Locate (CompromiseDate(0), CompromiseDate(t),
613 DestroyDate(0), DestroyDate(t)). Same as above. As there is no exit transition from the
614 Destroyed-Compromised state, the end of the range (t') is irrelevant.
- 615 • Match of a state at some point during a time range: Locate (CompromiseDate(0),
616 CompromiseDate(t'-1), DestroyDate(0), DestroyDate(t'-1)). Locate keys with a Compromise Date
617 at or before t'-1, and with a Destroy Date at or before t'-1. As there is no exit transition from the
618 Destroyed-Compromised state, the start of the range (t) is irrelevant.

619 3.19 ID Placeholder

620 A number of operations are affected by a mechanism referred to as the ID Placeholder. This is a
621 temporary variable consisting of a single Unique Identifier that is stored inside the server for the duration
622 of executing a batch of operations. The ID Placeholder is obtained from the Unique Identifier returned by
623 certain operations; the applicable operations are identified in [Table 1-Table 4](#), along with a list of
624 operations that accept the ID Placeholder as input.

Operation	ID Placeholder at the beginning of the operation	ID Placeholder upon completion of the operation (in case of operation failure, a batch using the ID Placeholder stops)
Create	-	ID of new Object
Create Key Pair	-	ID of new Private Key (ID of new Public Key may be obtained via a Locate)
Register	-	ID of newly registered Object
Derive Key	- (multiple Unique Identifiers may be specified in the request)	ID of new Symmetric Key
Locate	-	ID of located Object
Get	ID of Object	no change
Request Object	ID of Object	no change
Validate	-	-
Get Attributes List/Modify/Add/Delete	ID of Object	no change
Activate	ID of Object	no change
Revoke	ID of Object	no change
Destroy	ID of Object	no change
Archive/Recover	ID of Object	no change

Certify	ID of Public Key	ID of new Certificate
Re-certify	ID of Certificate	ID of new Certificate
Re-key	ID of Symmetric Key to be rekeyed	ID of new Symmetric Key
Obtain Lease	ID of Object	no change
Get Usage Allocation	ID of Key	no change
Check	ID of Object	no change

625 **Table 1: ID Placeholder Prior to and Resulting from a KMIP Operation**

626 3.20 Key Block

627 The protocol uses the Key Block structure to transport a key to the client or server. This Key Block
628 consists of the Key Value Type, the Key Value, and the Key Wrapping Data. The Key Value Type
629 identifies the format of the Key Material, e.g., Raw format or Transparent Key structure. The Key Value
630 consists of the Key Material and optional attributes. The Key Wrapping Data provides information about
631 the wrapping key and the wrapping mechanism, and is returned only if the client requests the Key Value
632 to be wrapped by specifying the Key Wrapping Specification inside the Get Request Payload. The Key
633 Wrapping Data may also be included inside the Key Block if the client registers a wrapped key.

634 The protocol allows any attribute to be included inside the Key Value and allows these attributes to be
635 cryptographically bound to the Key Material (i.e., by signing, MACing, encrypting, or both encrypting and
636 signing/MACing the Key Value). Some of the attributes that may be included include the following:

- 637 • Unique Identifier – uniquely identifies the key
- 638 • Cryptographic Algorithm (e.g., AES, 3DES, RSA) – this attribute is either specified inside the Key
639 Block structure or the Key Value structure.
- 640 • Cryptographic Length (e.g., 128, 256, 2048) – this attribute is either specified inside the Key
641 Block structure or the Key Value structure
- 642 • Cryptographic Usage Mask– identifies the cryptographic usage of the key (e.g., Encrypt, Wrap
643 Key, Export)
- 644 • Cryptographic Parameters – provides additional parameters for determining how the key may be
645 used
 - 646 – Block Cipher Mode (e.g., CBC, NISTKeyWrap, GCM) – this parameter identifies the mode of
647 operation, including block cipher-based MACs or wrapping mechanisms
 - 648 – Padding Method (e.g., OAEP, X9.31, PSS) – identifies the padding method and if applicable
649 the signature or encryption scheme.
 - 650 – Hashing Algorithm (e.g., SHA-256) – identifies the hash algorithm to be used with the
651 signature/encryption mechanism or Mask Generation Function; note that the different HMACs
652 are defined individually as algorithms and do not require the Hashing Algorithm parameter to
653 be set
 - 654 – **Key** Role Type – Identifies the financial key role (e.g., DEK, KEK)
- 655 • State (e.g., Active)
- 656 • Dates (e.g., Activation Date, Process Start Date, Protect Stop Date)
- 657 • Custom Attribute – allows vendors and clients to define vendor-specific attributes; may also be
658 used to prevent replay attacks by setting a nonce

659 3.21 Using Wrapped Keys with KMIP

660 KMIP provides the option to register and get keys in wrapped format. Clients request the server to return
661 a wrapped key by including the Key Wrapping Specification in the Get Request Payload. Similarly, clients
662 register a wrapped key by including the Key Wrapping Data in the Register Request Payload. The
663 Wrapping Method identifies the type of mechanism used to wrap the key, but does not identify the
664 algorithm or block cipher mode. It is possible to determine these from the attributes set for the specified
665 Encryption Key or MAC/Signing Key. If a key has multiple Cryptographic Parameters set, clients may
666 include the applicable parameters in Key Wrapping Specification. If omitted, the server chooses the
667 Cryptographic Parameter attribute with the lowest index.

668 The Key Value includes both the Key Material and, optionally, attributes of the key; these may be
669 provided by the client in the Register Request Payload; the server only includes attributes when
670 requested in the Key Wrapping Specification of the Get Request Payload. The Key Value may be
671 encrypted, signed/MACed, or both encrypted and signed/MACed (and vice versa). In addition, clients
672 have the option to request or import a wrapped Key Block according to standards, such as ANSI TR-31,
673 or vendor-specific key wrapping methods.

674 It is important to note that if the Key Wrapping Specification is included in the Get Request Payload, the
675 Key Value may not necessarily be encrypted. If the Wrapping Method is MAC/sign, the returned Key
676 Value is in plaintext, and the Key Wrapping Data includes the MAC or Signature of the Key Value.

677 Prior to wrapping or unwrapping a key, the server should verify that the wrapping key is allowed to be
678 used for the specified purpose. For example, if the Unique ID of a symmetric key is specified used for key
679 encryption in the Key Wrapping Specification inside the response to a Get request, the symmetric key
680 should have the "Wrap Key" bit set in its Cryptographic Usage Mask. Similarly, if the client registers a
681 signed key, the server should verify that the Signature Key, as specified by the client inside the Key
682 Wrapper Data, has the "Verify" bit set in the Cryptographic Usage Mask. If the wrapping key is not
683 permitted to be used for the requested purpose (e.g., when the Cryptographic Usage Mask is not set), the
684 server should return the Operation Failed error.

685 3.21.1 Encrypt-only Example with a Symmetric Key as an Encryption Key 686 for a Get Request and Response

687 The client sends a Get request to obtain a key that is stored on the server. When the client sends a Get
688 request to the server, a Key Wrapping Specification may be included. If a Key Wrapping Specification is
689 included in the Get request, and a client wants the requested key and its Cryptographic Usage Mask
690 attribute to be wrapped with using AES key wrap, the client includes the following information in the Key
691 Wrapping Specification:

- 692 • Wrapping Method: Encrypt
- 693 • Encryption Key Information
 - 694 – Unique Key ID: Key ID of the AES wrapping key
 - 695 – Cryptographic Parameters: The Block Cipher Mode is NISTKeyWrap (not necessary if default
 - 696 block cipher mode for wrapping key is NISTKeyWrap)
- 697 • Attribute Name: Cryptographic Usage Mask

698 The server uses the Unique Key ID specified by the client to determine the attributes set for the proposed
699 wrapping key. For example, the algorithm of the wrapping key is not explicitly specified inside the Key
700 Wrapping Specification. The -the server determines the algorithm to be used for wrapping the key by
701 identifying the Algorithm attribute set for the specified Encryption Key.

702 The Cryptographic Parameters attribute should be specified by the client if multiple instances of the
703 Cryptographic Parameters exist, and the lowest index does not correspond to the NIST key wrap mode of
704 operation. The server should verify that the AES wrapping key has NISTKeyWrap set as an allowable
705 Block Cipher Mode, and that the "Wrap Key" bit is set in the Cryptographic Usage Mask.

706 If the correct data was provided to the server, and no conflicts exist, the server AES key wraps the Key
707 Value (both the Key Material and the Cryptographic Usage Mask attribute) for the requested key
708 with using the AES key wrap algorithm and wrapping key specified in the Encryption Key Information. The

709 | ~~wrapped key; the Key Value contains both the Key Material and the Cryptographic Usage Mask attribute,~~
710 | ~~and return the encrypted result (byte string) is returned as the Key Value in the Key Block of the server's~~
711 | ~~response inside the Key Value of the Key Block.~~

712 | The Key Wrapping Data of the Key Block in the Get Response Payload includes the same data as
713 | specified in the Key Wrapping Specification of the Get Request Payload except for the Attribute Name.

714 | **3.21.2 Encrypt-only Example with a Symmetric Key as an Encryption Key** 715 | **for a Register Request and Response**

716 | The client sends a Register request to the server and includes the wrapped key and the ~~Unique~~unique ID
717 | of the wrapping key inside the Request Payload. The wrapped key is provided to the server inside the
718 | Key Block. The Key Block includes the Key Value Type, the Key Value, and the Key Wrapping Data. The
719 | Key Value Type identifies the format of the Key Material, the Key Value consists of the Key Material and
720 | optional attributes that may be included to cryptographically bind the attributes to the Key Material, and
721 | the Key Wrapping Data identifies the wrapping mechanism and the encryption key used to wrap the
722 | object and the wrapping mechanism.

723 | Similar to the example in 3.21.1, the key is wrapped using the AES key wrap. The Key Value includes four
724 | attributes: Cryptographic Algorithm, Cryptographic Length, Cryptographic Parameters, and Cryptographic
725 | Usage Mask.

726 | The Key Wrapping Data includes the following information:

- 727 | • Wrapping Method: Encrypt
- 728 | • Encryption Key Information
 - 729 | – Unique Key ID: Key ID of the AES wrapping key
 - 730 | – Cryptographic Parameters: The Block Cipher Mode is NISTKeyWrap (not necessary if default
731 | block cipher mode for wrapping key is NISTKeyWrap)

732 | Attributes do not need to be specified in the Key Wrapping Data. When registering a wrapped Key Value
733 | with attributes, clients may include these attributes inside the Key Value without specifying them inside
734 | the Template-Attribute.

735 | Prior to unwrapping the key, the server determines the wrapping algorithm from the Algorithm attribute set
736 | for the specified Unique ID in the Encryption Key Information. The server verifies that the wrapping key
737 | may be used for the specified purpose. In particular, if the client includes the Cryptographic Parameters in
738 | the Encryption Key Information, the server verifies that the specified Block Cipher Mode is set for the
739 | wrapping key. The server also verifies that the wrapping key has the "Unwrap Key" bit set in the
740 | Cryptographic Usage Mask.

741 | The Register Response Payload includes the Unique ID of the newly registered key and an optional list of
742 | attributes that were implicitly set by the server.

743 | **3.21.3 Encrypt-only Example with an Asymmetric Key as an Encryption** 744 | **Key for a Get Request and Response**

745 | The client sends a Get request to obtain a key (either symmetric or asymmetric) that is stored on the
746 | server. When the client sends a Get request to the server, a Key Wrapping Specification may be
747 | included. If a Key Wrapping Specification is included, and the key is to be wrapped with an RSA public
748 | key using the OAEP encryption scheme, the client includes the following information in the Key Wrapping
749 | Specification. Note that for this example, attributes for the requested key are not requested.

- 750 | • Wrapping Method: Encrypt
- 751 | • Encryption Key Information
 - 752 | – Unique Key ID: Key ID of the RSA public key
 - 753 | – Cryptographic Parameters:
 - 754 | Padding Method: OAEP
 - 755 | Hashing Algorithm: SHA-256

756 The Cryptographic Parameters attribute is specified by the client if multiple instances of Cryptographic
757 Parameters exist for the wrapping key, and the lowest index does not correspond to the associated
758 padding method. The server should verify that the specified Cryptographic Parameters in the Key
759 Wrapping Specification and the “Wrap Key” bit in the Cryptographic Usage Mask are set for the
760 corresponding wrapping key.

761 The Key Wrapping Data returned by the server in the Key Block of the Get Response Payload includes
762 the same data as specified in the Key Wrapping Specification of the Get Request Payload.

763 For both OAEP and PSS, KMIP currently assumes that the Hashing Algorithm specified in the
764 Cryptographic Parameters of the Get request is used for both the Mask Generation Function (MGF) and
765 hashing data. The example above requires the server to use SHA-256 for both purposes.

766 **3.21.4 MAC-only Example with an HMAC Key as an Authentication Key for** 767 **a Get Request and Response**

768 The client sends a Get request to obtain a key that is stored on the server. When the client sends a Get
769 request to the server, a Key Wrapping Specification may be included. If a key and Custom Attribute (i.e.,
770 x-Nonce) is to be MACed with HMAC SHA-256, the following Key Wrapping Specification is specified:

- 771 • Wrapping Method: MAC/sign
- 772 • MAC/Signature Key Information
 - 773 – Unique Key ID: Key ID of the MACing key (note that the algorithm associated with this key
 - 774 would be HMAC-256)
- 775 • Attribute Name: x-Nonce

776 For HMAC, no Cryptographic Parameters need to be specified, since the algorithm, including the hash
777 function, may be determined from the Algorithm attribute set for the specified MAC Key. The server
778 should verify that the HMAC key has the “MAC Generate” bit set in the Cryptographic Usage Mask. Note
779 that an HMAC key does not require the “Wrap Key” bit to be set in the Cryptographic Usage Mask.

780 The server creates an HMAC value over the Key Value if the specified MACing key may be used for the
781 specified purpose and no conflicts exist. The Key Value is returned in plaintext, and the Key Block
782 includes the following Key Wrapping Data:

- 783 • Wrapping Method: MAC/sign
- 784 • MAC/Signature Key Information
- 785 • Unique Key ID: Key ID of the MACing key
- 786 • MAC/Signature: HMAC result of the Key Value

787 In the example, the custom attribute x-Nonce was included to help clients, who are relying on the proxy
788 model, to detect replay attacks. End-clients, who communicate with the key management server, may not
789 support ~~SSL/TLS~~ and may not be able to rely on the message protection mechanisms provided by a
790 security protocol. An alternative approach for these clients would be to use the custom attribute ~~may be~~
791 created to hold a random number, counter, nonce, date, or time. The custom attribute needs to be
792 created before requesting the server to return a wrapped key and is recommended to be set if clients
793 frequently wrap/sign the same key with the same wrapping/signing key.

794 **3.21.5 Registering a Wrapped Key as an Opaque Cryptographic Object**

795 Clients may want to register and store a wrapped key on the server without the server being able to
796 unwrap the key (i.e., the wrapping key is not known to the server). Instead of storing the wrapped key as
797 an opaque object, clients have the option to store the wrapped key inside the Key Block as an opaque
798 cryptographic object, i.e., the wrapped key is registered as a managed cryptographic object, but the
799 encoding of the key is unknown to the server. Registering an opaque cryptographic object allows clients
800 to set all the applicable attributes that apply to cryptographic objects (e.g., Cryptographic Algorithm and
801 Cryptographic Length),

802 Opaque cryptographic objects are set by specifying the following inside the Key Block structure:

- 803 • Key Format Type: Opaque
804 • Key Material: Wrapped key as a Byte String
805 The Key Wrapping Data does not need to be specified.

806 3.22 Object Group

807 The key management system may specify rules for valid group names which may be created by the
808 client. Clients are informed of such rules by a mechanism that is not specified by [\[KMIP-Spec\]](#). In the
809 protocol, the group names themselves are character strings of no specified format. Specific key
810 management system implementations may choose to support hierarchical naming schemes or other
811 syntax restrictions on the names. Groups may be used to associate objects for a variety of purposes. A
812 set of keys used for a common purpose, but for different time intervals, may be linked by a common
813 Object Group. Servers may create predefined groups and add objects to them independently of client
814 requests.

815 3.23 Certify and Re-certify

816 The key management system may contain multiple embedded CAs or may have access to multiple
817 external CAs. How the server routes a certificate request to a CA is vendor-specific and outside the scope
818 of KMIP. If the server requires and supports the capability for clients to specify the CA to be used for
819 signing a Certificate Request, then this information may be provided by including the Certificate Issuer
820 attribute in the Certify or Re-certify request.

821 [\[KMIP-Spec\]](#) supports multiple options for submitting a certificate request to the key management server
822 within a Certify or Re-Certify operation. It is a vendor decision as to whether the key management server
823 offers certification authority (CA) functionality or proxies the certificate request onto a separate CA for
824 processing. The type of certificate request formats supported is also a vendor decision, and this may, in
825 part, be based upon the request formats supported by any CA to which the server proxies the certificate
826 requests.

827 All certificate request formats for requesting X.509 certificates specified in [\[KMIP-Spec\]](#) (i.e., PKCS#10,
828 PEM and CRMF) provide a means for allowing the CA to verify that the client that created the certificate
829 request possesses the private key corresponding to the public key in the certificate request. This is
830 referred to as Proof-of-Possession (POP). However, it should be noted that in the case of the CRMF
831 format, some CAs may not support the CRMF POP option, but instead rely upon the underlying certificate
832 management protocols (i.e., CMP and CMC) to provide POP. In the case where the CA does not support
833 POP via the CRMF format (including CA functionality within the key management server), an alternative
834 certificate request format (i.e., PKCS#10, PEM) would need to be used if POP needs to be verified.

835 3.24 Specifying Attributes during a Create Key Pair Operation

836 The Create Key Pair operation allows clients to specify attributes using the Common Template-Attribute,
837 Private Key Template-Attribute, and Public Key Template-Attribute. The Common Template-Attribute
838 object includes a list of attributes that apply to both the public and private key. Attributes that are not
839 common to both keys may be specified using the Private Key Template-Attribute or Public Key Template-
840 Attribute. If a single-instance attribute is specified in multiple Template-Attribute objects, the server obeys
841 the following order of precedence:

- 842 1. Attributes specified explicitly in the Private and Public Key Template-Attribute, then
- 843 2. Attributes specified via templates in the Private and Public Key Template-Attribute, then
- 844 3. Attributes specified explicitly in the Common Template-Attribute, then
- 845 4. Attributes specified via templates in the Common Template-Attribute

846 **3.24.1 Example of Specifying Attributes during the Create Key Pair**
847 **Operation**

848 A client specifies several attributes in the Create Key Pair Request Payload. The Common Template-
849 Attribute includes the template name RSACom and other explicitly specified common attributes:

850 Common Template-Attribute

- 851 • RSACom Template
 - 852 – Cryptographic Algorithm: RSA
 - 853 – Cryptographic Length: 2048
 - 854 – Cryptographic Parameters: Padding Method OAEP
 - 855 – Custom Attribute: x-Serial 1234
 - 856 – Object Group: Key encryption group 1
- 857 • Attribute
 - 858 – Cryptographic Length: 4096
 - 859 – Cryptographic Parameters: Padding Method PKCS1 v1.5
 - 860 – Custom Attribute: x-ID 56789

861 The Private Key Template-Attribute includes the template name RSAPriv and other explicitly-specified
862 private key attributes:

863 Private Key Template-Attribute

- 864 • RSAPriv Template
 - 865 – Object Group: Key encryption group 2
- 866 • Attribute
 - 867 – Cryptographic Usage Mask: Unwrap Key
 - 868 – Name: PrivateKey1

869 The Public Key Template Attribute includes explicitly-specified public key attributes:

870 Public Key Template-Attribute

- 871 • Attribute
 - 872 – Cryptographic Usage Mask: Wrap Key
 - 873 – Name: PublicKey1

874
875 Following the attribute precedence rule, the server creates a 4096-bit RSA key. The following client-
876 specified attributes are set:

877 Private Key

- 878 • Cryptographic Algorithm: RSA
- 879 • Cryptographic Length: 4096
- 880 • Cryptographic Parameters: OAEP
- 881 • Cryptographic Parameters: PKCS1 v1.5
- 882 • Cryptographic Usage Mask: Unwrap Key
- 883 • Custom Attribute: x-Serial 1234
- 884 • Custom Attribute: x-ID 56789
- 885 • Object Group: Key encryption group 1
- 886 • Object Group: Key encryption group 2
- 887 • Name: PrivateKey1

888 Public Key

- 889 • Cryptographic Algorithm: RSA
- 890 • Cryptographic Length: 4096
- 891 • Cryptographic Parameters: OAEP
- 892 • Cryptographic Parameters: PKCS1 v1.5
- 893 • Cryptographic Usage Mask: Wrap Key
- 894 • Custom Attribute: x-Serial 1234
- 895 • Custom Attribute: x-ID 56789
- 896 • Object Group: Key encryption group 1
- 897 • Name: PublicKey1

898 3.25 Registering a Key Pair

899 During a Create Key Pair operation, a Link Attribute is automatically created by the server for each object
900 (i.e., a link is created from the private key to the public key and vice versa). Certain attributes are the
901 same for both objects and are set by the server while creating the key pair. The KMIP protocol does not
902 support an equivalent operation for registering a key pair. Clients are able to register the objects
903 independently and manually set the Link attributes to make the server aware that these keys are
904 associated with each other. When the Link attribute is set for both objects, the server should verify that
905 the registered objects indeed correspond to each other and apply similar restrictions as if the key pair was
906 created on the server.

907 Clients should perform the following steps when registering a key pair:

- 908 1. Register the public key and set all associated attributes:
 - 909 a. Cryptographic Algorithm
 - 910 b. Cryptographic Length
 - 911 c. Cryptographic Usage Mask
- 912 2. Register the private key and set all associated attributes
 - 913 a. Cryptographic Algorithm is the same for both public and private key
 - 914 b. Cryptographic Length is the same for both public and private key
 - 915 c. Cryptographic Parameters may be set; if set, the value is the same for both the public and
916 private key
 - 917 d. Cryptographic Usage Mask is set, but does not contain the same value for both the public
918 and private key
 - 919 e. Link is set with Link Type *Public Key Link* and the Linked Object Identifier of the
920 corresponding Public Key
 - 921 f. Link is set for the Public Key with Link Type *Private Key Link* and the Linked Object Identifier
922 of the corresponding Private Key

923 3.26 Non-Cryptographic Objects

924 The KMIP protocol allows clients to register Secret Data objects. Secret Data objects may include
925 passwords or data that are used to derive keys.

926 KMIP defines Secret Data as cryptographic objects. Even if the object is not used for cryptographic
927 purposes, clients still set certain attributes, such as the Cryptographic Usage Mask, for this object unless
928 otherwise stated. Similarly, servers set certain attributes for this object, including the Digest, State, and
929 certain Date attributes, even if the attributes seem relevant only for cryptographic objects.

930 When registering a Secret Data object, the following attributes are set by the server:

- 931 • Unique Identifier
- 932 • Object Type
- 933 • Digest
- 934 • State
- 935 • Initial Date
- 936 • Last Change Date

937 When registering a Secret Data object for non-cryptographic purposes, the following attributes are set by
 938 either the client or the server:

- 939 • Cryptographic Usage Mask

940 3.27 Asymmetric Concepts with Symmetric Keys

941 The Cryptographic Usage Mask attribute is intended to adequately support asymmetric concepts using
 942 symmetric keys. This is fairly common practice in established crypto systems: the MAC is an example of
 943 an operation where a single symmetric key is used at both ends, but policy dictates that one end may
 944 only generate cryptographic tokens using this key (the MAC) and the other end may only verify tokens.
 945 The security of the system fails if the verifying end is able to use the key to perform generate operations.

946 In these cases it is not sufficient to describe the usage policy on the keys in terms of cryptographic
 947 primitives like “encrypt” vs. “decrypt” or “sign” vs. “verify”. There are two reasons why this is the case.

- 948 • In some of these operations, such as MAC generate and verify, the same cryptographic primitive
 949 is used in both of the complementary operations. MAC generation involves computing and
 950 returning the MAC, while MAC verification involves computing that same MAC and comparing it
 951 to a supplied value to determine if they are the same. Thus, both generation and verification use
 952 the “encrypt” operation, and the two usages are not able to be distinguished by considering only
 953 “encrypt” vs. “decrypt”.
- 954 • Some operations which require separate key types use the same fundamental cryptographic
 955 primitives. For example, encryption of data, encryption of a key, and computation of a MAC all
 956 use the fundamental operation “encrypt”, but in many applications, securely differentiated keys
 957 are used for these three operations. Simply looking for an attribute that permits “encrypt” is not
 958 sufficient.

959 Allowing the use of these keys outside of their specialized purposes may compromise security. Instead,
 960 specialized application-level permissions are necessary to control the use of these keys. KMIP provides
 961 several pairs of such permissions in the Cryptographic Usage Mask (3.14), such as:

MAC GENERATE MAC VERIFY	For cryptographic MAC operations. Although it is possible to compose certain MACs using a series of encrypt calls, the security of the MAC relies on the operation being atomic and specific.
GENERATE CRYPTOGRAM VALIDATE CRYPTOGRAM	For composite cryptogram operations such as financial CVC or ARQC. - To specify exactly which cryptogram the key is used for it is also necessary to specify a <i>role</i> for the key (see Section 3.6 “Cryptographic Parameters” in [KMIP-Spec]).
TRANSLATE ENCRYPT TRANSLATE DECRYPT TRANSLATE WRAP TRANSLATE UNWRAP	To accommodate secure routing of traffic and data. In many areas that rely on symmetric techniques (notably, but not exclusively financial networks), information is sent from place to place encrypted using shared symmetric keys. When encryption keys are changed, it is desirable for the change to be an atomic operation, otherwise distinct unwrap-wrap or decrypt-encrypt steps risk leaking the

	<p>plaintext data during the translation process.</p> <p><i>TRANSLATE ENCRYPT/DECRYPT</i> is used for data encipherment.</p> <p><i>TRANSLATE WRAP/UNWRAP</i> is used for key wrapping.</p>
--	--

962 **Table 2: Cryptographic Usage Masks Pairs**

963 In order to support asymmetric concepts using symmetric keys in a KMIP system, the server
 964 implementation needs to be able to differentiate between clients for generate operations and clients for
 965 verify operations. As indicated by Section 3 (“Attributes”) of [\[KMIP-Spec\]](#) there is a single key object in
 966 the system to which all relevant clients refer, but when a client requests that key, the server is able to
 967 choose which attributes (permissions) to send with it, based on the identity and configured access rights
 968 of that specific client. There is, thus, no need to maintain and synchronize distinct copies of the symmetric
 969 key – just a need to define access policy for each client or group of clients.

970 The internal implementation of this feature at the server end is a matter of choice for the vendor: storing
 971 multiple key blocks with all necessary combinations of attributes or generating key blocks dynamically are
 972 both acceptable approaches.

973 3.28 Application Specific Information

974 The Application Specific Information attribute is used to store data which is specific to the application(s)
 975 using the object. Some examples of Application Name Space and Application Data pairs are given below.

- 976 • SMIME, 'someuser@company.com'
- 977 • [TLSSSL](#), 'some.domain.name'
- 978 • Volume Identification, '123343434'
- 979 • File Name, 'secret.doc'
- 980 • Client Generated Key ID, '450994003'

981 The following Application Name Spaces are recommended:

- 982 • SMIME
- 983 • [TLS](#)
- 984 • [SSL](#)
- 985 • IPSEC
- 986 • HTTPS
- 987 • PGP
- 988 • Volume Identification
- 989 • File Name
- 990 • LTO4
- 991 • LIBRARY-LTO4

992 KMIP provides optional support for server-generated Application Data. Clients may request the server to
 993 generate the Application Data for the client by omitting Application Data while setting or modifying the
 994 Application Specific Information attribute. A server only generates the Application Data if the Application
 995 Data is completely omitted from the request, and the client-specified Application Name Space is
 996 recognized and supported by the server. An example for requesting the server to generate the Application
 997 Data is shown below:

```
998 AddAttribute(UID, AppSpecInfo{AppNameSpace='LIBRARY-LTO4'});
```

999 If the server does not recognize the name space, the “Application Name Space Not Supported” error is
 1000 returned to the client.

1001 If the Application Data is set to null, as shown in the example below, and the Application Name Space is
1002 recognized by the server, the server does not generate the Application Data for the client. The server
1003 stores the Application Specific Information attribute with the Application Data value set to null.
1004 `AddAttribute(UID, AppSpecInfo{AppNameSpace='LIBRARY-LTO4', AppData=null});`

1005 **3.29 Mutating Attributes**

1006 KMIP does not support server mutation of client-supplied attributes. If a server does not accept an
1007 attribute value that is being specified inside the request by the client, the server returns an error and
1008 specifies "Invalid Field" as Result Reason.

1009 Attributes that are not set by the client, but are implicitly set by the server as a result of the operation, may
1010 optionally be returned by the server in the operation response inside the Template-Attribute.

1011 If a client sets a time-related attribute to the current date and time (as perceived by the client), but as a
1012 result of a clock skew, the specified date of the attribute is earlier than the time perceived by the server,
1013 the server's policy will be used to determine whether to accept the "backdated attribute". KMIP does not
1014 require the server to fail a request if a backdated attribute is set by the client.

1015 If a server does not support backdated attributes, and cryptographic objects are expected to change state
1016 at the specified current date and time (as perceived by the client), clients are recommended to issue the
1017 operation that would implicitly set the date for the client. For example, instead of explicitly setting the
1018 Activation Date, clients could issue the Activate operation. This would require the server to set the
1019 Activation Date to the current date and time as perceived by the server.

1020 If it is not possible to set a date attribute via an operation, and the server does not support backdated
1021 attributes, clients need to take into account that potential clock skew issues may cause the server to
1022 return an error even if a date attribute is set to the client's current date and time.

1023 For additional information, refer to the sections describing the State attribute and the Time Stamp field in
1024 [\[KMIP-Spec\]](#).

1025 **3.30 Interoperable Key Naming for Tape**

1026 This section describes methods for creating and storing key identifiers that are interoperable across multi-
1027 vendor KMIP clients.

1028 **3.30.1 Native Tape Encryption by a KMIP Client**

1029 This method is primarily intended to promote interoperable key naming between tape library products
1030 which already support non-KMIP key managers, where KMIP support is being added.

1031 When those existing library products become KMIP clients, a common method for naming and storing
1032 keys may be used to support moving tape cartridges between the libraries, and successfully retrieving
1033 keys, assuming that the clients have appropriate access privileges. The library clients may be from
1034 multiple vendors, and may be served by a KMIP key manager from a different vendor.

1035 **3.30.1.1 Method Overview**

- 1036 • The method uses the KMIP Application Specific Information (ASI) attribute's Application Data field
1037 to store the key name. The ASI Application Name Space is used to identify the namespace (such
1038 as LIBRARY-LTO4).
- 1039 • The method also uses the tape format's Key Associated Data (KAD) fields to store the key name.
1040 Tape formats may provide both authenticated and unauthenticated storage for the KAD data. This
1041 method ensures optimum utilization of the authenticated KAD data when the tape format supports
1042 authentication.
- 1043 • The method supports both client-generated and server-generated key names.
- 1044 • The method, in many cases, is backward-compatible if tapes are returned to a non-KMIP key
1045 manager environment.

- 1046
- 1047
- 1048
- 1049
- 1050
- Key names stored in the KMIP server's ASI attribute are always text format. Key names stored on the KMIP client's KAD fields are always numeric format, due to space limitations of the tape format. The method basically consists of implementing a specific algorithm for converting between text and numeric formats.
 - The algorithm used by this conversion is reversible.

1051 **3.30.1.2 Definitions**

- 1052
- 1053
- 1054
- 1055
- 1056
- 1057
- 1058
- 1059
- 1060
- 1061
- 1062
- 1063
- 1064
- 1065
- 1066
- Key Associated Data (KAD). Part of the tape format. May be segmented into authenticated and unauthenticated fields. KAD usage is detailed in the SCSI SSC-3 standard from the T10 organization.
 - Application Specific Information (ASI). A KMIP attribute.
 - Hexadecimal numeric characters. Case-sensitive, printable, single byte ASCII characters representing the numbers 0 through 9 and uppercase alpha A through F. (US-ASCII characters 30h-39h and 41h-46h).
Hexadecimal numeric characters are always paired, each pair representing a single 8-bit numeric value. A leading zero character is provided, if necessary, so that every byte in the tape's KAD is represented by exactly 2 hexadecimal numeric characters.
 - N(k). The number of bytes in the tape format's combined KAD fields (both authenticated and unauthenticated).
 - N(a), N(u). The number of bytes in the tape format's authenticated, and unauthenticated KAD fields, respectively.

1067 **3.30.1.3 Algorithm 1. Numeric to text direction (tape format's KAD to KMIP ASI)**

1068

1069 Description: All information contained in the tape format's KAD fields is converted to a null-terminated ASCII string consisting of hexadecimal numeric character pairs. First, the unauthenticated KAD data is converted to text. Then, the authenticated KAD data is converted and appended to the end of the string. The string is then null-terminated.

1070

1071

1072

1073

1074 Implementation Example:

- 1075
- 1076
- 1077
- 1078
- 1079
- 1080
- 1081
- 1082
- 1083
- 1084
- 1085
- 1086
- 1087
- 1088
- 1089
- 1090
1. Define an input buffer sized for N(k). For LTO4, N(k) is 44 bytes (12 bytes authenticated, 32 unauthenticated).
 2. Define an output buffer sufficient to contain a null-terminated string with a maximum length of $2*N(k)+1$ bytes.
 3. Define the standard POSIX (also known as C) locale. Each character in the string is a single-byte US-ASCII character.
 4. Copy the tape format's KAD data, from the unauthenticated KAD field first, to the input buffer. Effectively, the first byte (byte 0) of the input buffer is the first byte of unauthenticated KAD. Bytes from the authenticated KAD are concatenated, after the unauthenticated bytes.
 5. For each byte in the input buffer, convert to US-ASCII as follows:
 - a. Convert the byte's value to exactly 2 hexadecimal numeric characters, including a leading 0 where necessary. Append these 2 numeric characters to the output buffer, with the high-nibble represented by the left-most hexadecimal numeric character.
 - b. After all byte values have been converted, null terminate the output buffer.
 6. When storing the string to the KMIP server, use the object's ASI attribute's Application Data field. Store the namespace (such as LIBRARY-LTO4) in the ASI attribute's Application Name Space field.

1091 **3.30.1.4 Algorithm 2. Text to numeric direction (KMIP ASI to tape format's**
1092 **KAD)**

1093 Description: Hexadecimal numeric character pairs in the null-terminated ASCII string are converted to
1094 single byte numeric values, and stored in the tape format's KAD fields. The authenticated KAD field is
1095 populated first, from a sub-string consisting of the last 2*N(a) characters in the full string. Any remaining
1096 characters in the string are converted and stored to the unauthenticated KAD field. The null termination
1097 byte is not converted.
1098

1099 Implementation Example:

- 1100 1. Obtain the key's name from the KMIP server's ASI attribute for that object. Copy the null terminated
1101 string to an input buffer of size 2*N(k) + 1 bytes. For LTO4, an 89 character string, including null
1102 termination, is sufficient for all possible key descriptors when names are directly referenced.
- 1103 2. Define output buffers for unauthenticated KAD, and authenticated KAD, of size N(u) and N(a)
1104 respectively. For LTO4, this would be 32 bytes of unauthenticated data, and 12 bytes of authenticated
1105 data.
- 1106 3. Define the standard POSIX (also known as C) locale. Each character in the string is a single-byte US-
1107 ASCII character.
- 1108 4. First, populate the authenticated KAD buffer, converting a sub-string consisting of the last 2*N(a)
1109 characters of the full string, not including the null termination byte.
- 1110 5. When the authenticated KAD is filled, next populate the unauthenticated KAD buffer, by converting
1111 the remaining hexadecimal character pairs in the string.

1112 **3.30.1.5 Example Output**

1113 The following are examples illustrating some results of this method. In the following examples, the sizes
1114 of the KAD for LTO4 are used. Different tape formats may utilize different KAD sizes.

1115

1116 Example 1. Full combined KAD

1117

1118 This LTO4 tape's combined KAD contains the following data (represented in hexadecimal). For LTO4, the
1119 unauthenticated KAD contains 32 bytes, and the authenticated KAD contains 12 bytes.
1120

1121 Example 1a. Hexadecimal numeric data from a tape's KAD.

1122 Shaded data is authenticated by the tape drive.

1123

1124 02 04 17 11 39 43 42 36 30 41 33 34 39 31 44 33

1125 41 41 43 36 32 42 07 F6 54 54 32 36 30 38 4C 34

1126 30 30 30 39 30 35 32 38 30 34 31 32

1127

1128 The algorithm converts the numeric KAD data to the following 89 character null-terminated string for
1129 storage in the Application Data field of a KMIP object's Application Specific Information attribute. The ASI
1130 Application Name Space contains "LIBRARY-LTO4".

1131

1132 Example 1b. Text string from KMIP ASI Application Data.

1133 Shaded characters are derived from authenticated data. The null character is represented as

1134 <null>

1135

1136 0204171139434236304133343931443341414336324207F65454323630384C343030303930353
1137 23830343132<null>
1138

1139 Example 1c. The hexadecimal values of the 89 US-ASCII characters in string 1b, from the KMIP
1140 ASI Application Data. Note: these values are always in the range 30h-39h, or in the range 41h-
1141 46h, or the 0h null.

1142 30 32 30 34 31 37 31 31 33 39 34 33 34 32 33 36 33 30 34 31 33 33 33 34 33 39 33 31 34 34 33
1143 33 34 31 34 31 34 33 33 36 33 32 34 32 30 37 46 36 35 34 35 34 33 32 33 36 33 30 33 38 34 43
1144 33 34 33 30 33 30 33 30 33 39 33 30 33 35 33 32 33 38 33 30 33 34 33 31 33 32 00

1145

1146 For the reverse transformation, a client would retrieve the string in 1b from the server, derive the numeric
1147 values shown in 1a, and store them to the tape format's KAD data. First, the sub-string containing the
1148 right-most 24 characters of the full 1b string are used to derive the 12-byte authenticated KAD. The
1149 remaining characters are used to derive the 32-byte unauthenticated KAD.

1150

1151 Example 2. Authenticated KAD only

1152 This LTO4 tape's KAD contains the following data (represented in hexadecimal), all 12 bytes obtained
1153 from the authenticated KAD field. There is no unauthenticated KAD data.

1154

1155 Example 2a. Hexadecimal numeric data from a tape's KAD.

1156 Shaded data is authenticated.

1157

1158 17 48 33 C6 20 42 10 A7 E8 05 F8 C7

1159 The algorithm converts the numeric KAD data to the following 24 character null-terminated string, for
1160 storage in the Application Data field of a KMIP object's Application Specific Information attribute.

1161

1162 Example 2b. Text string from KMIP ASI Application Data.

1163 Shaded characters are derived from authenticated data. The null character is represented as
1164 <null>

1165

1166 174833C6204210A7E805F8C7<null>

1167

1168 For the reverse transformation, a client would derive the numeric values in 2a, and store them to the tape
1169 format's KAD data. The right-most 24 characters of the string in 2b are used to derive the 12 byte
1170 authenticated KAD. In this example, there is no unauthenticated KAD data.

1171

1172 Example 3. Partially filled authenticated KAD originating from a non-KMIP method

1173 This LTO4 tape's KAD contains the following data (represented in hexadecimal). The unauthenticated
1174 KAD contains 10 bytes, and the authenticated KAD contains 8 bytes.

1175

1176 Since the authenticated KAD was not filled, but the unauthenticated data was populated, the method
1177 creating this key name is potentially not backward-compatible with the KMIP key naming method. See
1178 backward-compatibility assessment, below.

1179

1180 Example 3a. Hexadecimal numeric data from a non-KMIP tape's KAD.

1181 Shaded data is authenticated.

1182

1183 02 04 17 11 39 43 42 36 30 41 30 30 30 39 30 35

1184 32 38

1185

1186 The algorithm converts the numeric KAD data to the following 36 character null-terminated string, for
1187 storage in the Application Data field of a KMIP object's Application Specific Information attribute.

1188

1189 Example 3b. Text string from KMIP ASI Application Data.

1190 Shaded characters are derived from authenticated data. The null character is represented as
1191 <null>

1192

1193 020417113943423630413030303930353238<null>

1194

1195 For the reverse transformation, a client would derive the same numeric values shown in 3a, and store
1196 them to the tape's KAD. But their storage locations within the KAD now differs (see 3c). The right-most 24
1197 characters from the text string in 3b are used to derive the 12-byte authenticated KAD. The remaining
1198 characters are used to fill the 32-byte unauthenticated KAD.

1199

1200 Example 3c. Hexadecimal numeric data from a tape's KAD.

1201 Shaded data is authenticated.

1202

1203 02 04 17 11 39 43 42 36 30 41 30 30 30 39 30 35

1204 32 38

1205 3.30.1.6 Backward-compatibility assessment

1206 Where all the following conditions exist, a non-KMIP solution may encounter compatibility issues during
1207 the Read and Appended Write use cases.

1208 1. The tape format supports authenticated KAD, but the non-KMIP solution does not use, or only
1209 partially uses, the authenticated KAD field.

1210 2. The non-KMIP solution is sensitive to data position within the combined KAD.

1211 3. The media was written in a KMIP environment, using this method, then moved to the non-KMIP
1212 environment.

1213 3.31 Revocation Reason Codes

1214 The enumerations for the Revocation Reason attribute specified in KMIP (see table 9.1.3.2.17 in [\[KMIP-
1215 Spec\]](#)) are aligned with the Reason Code specified in X.509 and referenced in RFC 5280 with the
1216 following exceptions. The *certificateHold* and *removeFromCRL* reason codes have been excluded from
1217 [\[KMIP-Spec\]](#), since this version of KMIP does not support certificate suspension (putting a certificate
1218 hold) or unsuspension (removing a certificate from hold). The *aaCompromise* reason code has been
1219 excluded from [\[KMIP-Spec\]](#) since it only applies to attribute certificates, and, at this point of time, attribute
1220 certificates are considered out-of-scope for [\[KMIP-Spec\]](#). The *privilegeWithdrawn* reason code is
1221 included in [\[KMIP-Spec\]](#) since it may be used for either attribute or public key certificates. In the context
1222 of its use within KMIP it is assumed to only apply to public key certificates.

1223 3.32 Certificate Renewal, Update, and Re-key

1224 The process of generating a new certificate to replace an existing certificate may be referred to by
1225 multiple terms, based upon what data within the certificate is changed when the new certificate is created.
1226 In all situations, the new certificate includes a new serial number and new validity dates. [-\[KMIP-Spec\]](#)
1227 uses the following terminology which is aligned with the definitions found in IETF RFCs [\[RFC3647\]](#)[3647](#)
1228 and [\[RFC4949\]](#)[4949](#):

- 1229 • *Certificate Renewal*: The issuance of a new certificate to the subject without changing the subject
1230 public key or other information (except the serial number and certificate validity dates) in the
1231 certificate.
- 1232 • *Certificate Update*: The issuance of a new certificate, due to changes in the information in the
1233 certificate other than the subject public key.
- 1234 • *Certificate Rekey*: The generation of a new key pair for the subject and the issuance of a new
1235 certificate that certifies the new public key.

1236 The current KMIP Specification supports certificate renewals using the Re-Certify operation and certificate
1237 updates using the Certify operation. Support for certificate rekey is not currently supported by KMIP, since
1238 certificate rekey requires the ability to rekey an asymmetric key pair a capability not currently supported
1239 by KMIP. Support for rekey of asymmetric key pairs, along with certificate rekey, may be considered for a
1240 future KMIP release.

1241 3.33 Key Encoding

1242 Two parties receiving the same key as a Key BYTE STRING make use of the key in exactly the same
1243 way in order to interoperate. To ensure that, it is necessary to define a correspondence between the
1244 abstract syntax of Key and the notation in the standard algorithm description that defines how the key is
1245 used. The next sections establish that correspondence for the algorithms AES [\[FIPS197\]](#) and Triple-DES
1246 [\[SP800-67\]\[SP800-67\]](#).

Formatted: Ref term, Font: Not Bold, English (U.S.)

1247 3.33.1 AES Key Encoding

1248 [\[FIPS197\]](#) section 5.2, titled Key Expansion, uses the input key as an array of bytes indexed starting at 0.
1249 The first byte of the Key becomes the key byte in AES that is labeled index 0 in [\[FIPS197\]](#) and the other
1250 key bytes follow in index order.

1251 Proper parsing and key load of the contents of the Key for AES is determined by using the following Key
1252 byte string to generate and match the key expansion test vectors in [\[FIPS197\]](#) Appendix A for the 128-bit
1253 (16 byte) AES Cipher Key: 2B 7E 15 16 28 AE D2 A6 AB F7 15 88 09 CF 4F 3C.

1254 3.33.2 Triple-DES Key Encoding

1255 A Triple-DES key consists of three keys for the cryptographic engine (Key1, Key2, and Key3) that are
1256 each 64 bits (even though only 56 are used); the three keys are also referred to as a key bundle (KEY)
1257 [\[SP800-67\]\[SP800-67\]](#). A key bundle may employ either two or three mutually independent keys. When
1258 only two are employed (called two-key Triple-DES), then Key1 = Key3.

Formatted: Ref term, Font: Not Bold, English (U.S.)

1259 Each key in a Triple-DES key bundle is expanded into a key schedule according to a procedure defined in
1260 [\[SP800-67\]\[SP800-67\]](#) Appendix A. That procedure numbers the bits in the key from 1 to 64, with
1261 number 1 being the left-most, or most significant bit. The first byte of the Key is bits 1 through 8 of Key1,
1262 with bit 1 being the most significant bit. The second byte of the Key is bits 9 through 16 of Key1, and so
1263 forth, so that the last byte of the KEY is bits 57 through 64 of Key3 (or Key2 for two-key Triple-DES).

Formatted: Ref term, Font: Not Bold, English (U.S.)

1264 Proper parsing and key load of the contents of Key for Triple-DES is determined by using the following
1265 Key byte string to generate and match the key expansion test vectors in [\[SP800-67\]\[SP800-67\]](#) Appendix
1266 B for the key bundle:

Formatted: Ref term, Font: Not Bold, English (U.S.)

1267 Key1 = 0123456789ABCDEF
1268 Key2 = 23456789ABCDEF01
1269 Key3 = 456789ABCDEF0123

1270 3.34 Using the Same Asymmetric Key Pair in Multiple Algorithms

1271 There are mathematical relationships between certain asymmetric cryptographic algorithms such as the
1272 Digital Signature Algorithm (DSA) and Diffie-Hellman (DH) and their elliptic curve equivalents ECDSA and
1273 ECDH that allow the same asymmetric key pair to be used in both algorithms. In addition, one will notice
1274 overlaps in the key format used to represent the asymmetric key pair for each algorithm type.

1275 | Even though a single key pair may be used in multiple algorithms, the KMIP Specification has chosen to
1276 | specify separate key formats for representing the asymmetric key pair for use in each algorithm. This
1277 | approach keeps KMIP in line with the reference standards (e.g., NIST FIPS 186-3 [FIPS186-3], ANSI
1278 | X9.42 [X9.42], etc) from which the key formats for DSA, DH, ECDSA, etc. are obtained and the best
1279 | practice documents (e.g., NIST SP800-57 part 1 [SP800-57-1], NIST SP800-56A [SP800-56A], etc)
1280 | which recommend that a key pair only be used for one purpose.

Formatted: Indent: Left: 0 pt, First line: 0 pt,
Don't adjust space between Latin and Asian text

1281

4 Deferred KMIP Functionality

1282 The KMIP Specification is currently missing items that have been judged candidates for future inclusion in
1283 the specification. These items currently include:

- 1284 • Registration of Clients. This would allow in-band registration and management of clients, which
1285 currently may only be registered and/or managed using off-line mechanisms.
- 1286 • Client-requested specification of additional clients that are allowed to use a key. This requires
1287 coordinated identities between the client and server, and as such, is deferred until registration of
1288 clients is addressed.
- 1289 • Registration of Notifications. This would allow clients to specify, using an in-band mechanism,
1290 information and events that they wish to be notified of, and what mechanisms should be used for
1291 such notifications, possibly including the configuration of pushed cryptographic material. This
1292 functionality would assume the Registration of Clients as a prerequisite.
- 1293 • Key Migration. This would standardize the migration of keys from one HSM to another, using
1294 mechanisms already in the protocol or ones added for this purpose.
- 1295 • Server to Server key management. This would extend the protocol to support communication
1296 between key management servers in different key management domains, for purposes of
1297 exporting and importing cryptographic material and potentially policy information.
- 1298 • Multiple derived keys. This would allow the creation of multiple derived keys from one or more
1299 input keys. Note, however, that the current version of KMIP provides the capability to derive
1300 multiple keys and initialization vectors by creating a Secret Data object and specifying a
1301 cryptographic length equal to the total length of the derived objects.
- 1302 • XML encoding. Expression of KMIP in XML rather than in tag/type/length/value may be
1303 considered for the future.
- 1304 • Specification of Mask Generation Function. KMIP does not currently allow clients to specify the
1305 Mask Generation Function and assumes that encryption or signature schemes, such as OAEP or
1306 PSS, use MGF1 with the hash function as specified in the Cryptographic Parameters attribute.
1307 Client specification of MGFs may be considered for the future.
- 1308 • Certificate creation without client-provided Certificate Request. This would allow clients to request
1309 the server to perform the Certify or Re-certify operation from the specified key pair IDs without
1310 providing a Certificate Request.
- 1311 • Server monitoring of client status. This would enable the transfer of information about the client
1312 and its cryptographic module to the server. This information would enable the server to generate
1313 alarms and/or disallow requests from a client running component versions with known
1314 vulnerabilities.
- 1315 • Symmetric key pairs. Only a subset of the cryptographic usage bits of the Cryptographic Usage
1316 Mask attribute may be permitted for keys distributed to a particular client. KMIP does not currently
1317 address how to securely assign and determine the applicable cryptographic usage for a client.
- 1318 • Hardware-protected attribute. This attribute would allow clients and servers to determine if a key
1319 may only be processed inside a secure cryptographic device, such as an HSM. If this attribute is
1320 set, the key may only exist in cleartext within a secure hardware device, and all security-relevant
1321 attributes are bound to it in such a way that they may not be modified outside of such a secure
1322 device.
- 1323 • Alternative profiles for key establishment. Less capable end-clients may not be able to support
1324 TLS and should use a proxy to communicate with the key management system. The KMIP
1325 protocol does not currently support alternative profiles, nor does it allow end-clients relying on the
1326 proxy model to securely establish a key with the server.

- 1327
1328
1329
- Attribute mutation. The possibility for the server to use attribute values different than requested by the client if these values are not suitable for the server, and return these values in the response, instead of failing the request.
- 1330
1331
- Cryptographic Domain Parameters. KMIP allows a limited number of parameters to be specified during a Create Key Pair operation. Additional parameters may be considered for the future.
- 1332
1333
1334
- Re-key support for other cryptographic objects. The Re-key operation is currently restricted to symmetric keys. Applying Re-key to other cryptographic objects, such as asymmetric keys and certificates, may be considered for the future.
- 1335
1336
1337
- Certificate Suspension/Unsuspend. KMIP does not currently support certificate suspension (putting a certificate on hold) or unsuspension (removing a certificate from hold). Adding support for certificate suspension/unsuspension into KMIP may be considered for the future.
- 1338
1339
- Namespace registration. Establishing a registry for namespaces may be considered for the future.
- 1340
1341
1342
- Registering extensions to KMIP enumerations. Establishing a registry for extensions to defined KMIP enumerations, such as in support of profiles specific to IEEE P1619.3 or other organizations, may be considered for the future.

1343 In addition to the functionality listed above, the KMIP TC is interested in establishing a C&A (certification
1344 and accreditation) process for independent validation of claims of KMIP conformance. Defining and
1345 establishing this process is a candidate for work by the KMIP TC after V1.0.

1346

5 Implementation Conformance

1347 This document is intended to be informational only and as such has no conformance clauses. The
1348 | conformance requirements for the KMIP ~~Specifications~~specification can be found in the "KMIP
1349 Specification" document itself, at the URL noted on the cover page of this document.

1350

A. Acronyms

- 1351 The following abbreviations and acronyms are used in this document:
- 1352 3DES - Triple Data Encryption Standard specified in ANSI X9.52
- 1353 AES - Advanced Encryption Standard specified in FIPS 197
- 1354 ANSI - American National Standards Institute
- 1355 ARQC - Authorization Request Cryptogram
- 1356 ASCII - American Standard Code for Information Interchange
- 1357 CA - Certification Authority
- 1358 CBC - Cipher Block Chaining specified in NIST SP 800-38A
- 1359 CMC - Certificate Management Messages over CMS specified in RFC 5275
- 1360 CMP - Certificate Management Protocol specified in RFC 4210
- 1361 CRL - Certificate Revocation List specified in RFC 5280
- 1362 CRMF - Certificate Request Message Format specified in RFC 4211
- 1363 CVC - Card Verification Code
- 1364 DES - Data Encryption Standard specified in FIPS 46-3
- 1365 DEK - Data Encryption Key
- 1366 DH - Diffie-Hellman specified in ANSI X9.42
- 1367 FIPS - Federal Information Processing Standard
- 1368 GCM - Galois/Counter Mode specified in NIST SP 800-38D
- 1369 HMAC - Keyed-Hash Message Authentication Code specified in FIPS 198-1
- 1370 HSM - Hardware Security Module
- 1371 HTTP - Hyper Text Transfer Protocol
- 1372 HTTP(S) - Hyper Text Transfer Protocol (Secure socket)
- 1373 ID - Identification
- 1374 IP - Internet Protocol
- 1375 IPSec - Internet Protocol Security
- 1376 JKS - Java Key Store
- 1377 KEK - Key Encryption Key
- 1378 KMIP - Key Management Interoperability Protocol
- 1379 LTO4 - Linear Tape-Open 4
- 1380 MAC - Message Authentication Code
- 1381 MD5 - Message Digest 5 Algorithm specified in RFC 1321
- 1382 MGF - Mask Generation Function
- 1383 NIST - National Institute of Standards and Technology
- 1384 OAEP - Optimal Asymmetric Encryption Padding specified in PKCS#1
- 1385 PEM - Privacy Enhanced Mail specified in RFC 1421

- 1386 PGP - Pretty Good Privacy specified in RFC 1991
- 1387 PKCS - Public-Key Cryptography Standards
- 1388 POP - Proof of Possession
- 1389 POSIX - Portable Operating System Interface
- 1390 PSS - Probabilistic Signature Scheme specified in PKCS#1
- 1391 RACF - Remote Access Control Facility
- 1392 RSA - Rivest, Shamir, Adelman (an algorithm)
- 1393 SHA - Secure Hash Algorithm specified in FIPS 180-2
- 1394 SP - Special Publication
- 1395 | ~~SSL~~ ~~Secure Sockets Layer~~
- 1396 S/MIME - Secure/Multipurpose Internet Mail Extensions
- 1397 TCP - Transport Control Protocol
- 1398 TLS - Transport Layer Security
- 1399 TTLV - Tag, Type, Length, Value
- 1400 URI - Uniform Resource Identifier
- 1401 X.509 - Public Key Certificate specified in RFC 5280
- 1402 XML - Extensible Markup Language

1403

B. Acknowledgements

1404 The following individuals have participated in the creation of this specification and are gratefully
1405 acknowledged:

1406 Original Authors of the initial contribution:

- 1407 David Babcock, HP
- 1408 Steven Bade, IBM
- 1409 Paolo Bezoari, NetApp
- 1410 Mathias Björkqvist, IBM
- 1411 Bruce Brinson, EMC
- 1412 Christian Cachin, IBM
- 1413 Tony Crossman, Thales/nCipher
- 1414 Stan Feather, HP
- 1415 Indra Fitzgerald, HP

C. Revision History

Revision	Date	Editor	Changes Made
ed-0.98	2009-04-29	Indra Fitzgerald	Initial conversion of input document to OASIS format.
ed-0.98	2009-07-28	Indra Fitzgerald	Added clarifications, examples, and deferred items.
ed-0.98	2009-09-08	Indra Fitzgerald	Added approved proposals and incorporated Elaine Barker's comments.
ed-0.98	2009-09-23	Indra Fitzgerald	Removed KMIP Profiles section and incorporated the Interoperable Key Naming for Tape proposal.
ed-0.98	2009-09-24	Indra Fitzgerald	Removed the Conformance section; added additional Certificate Request and POP text to Certify and Re-certify; added the Revocation Reason Codes section.
draft-01	2009-10-07	Indra Fitzgerald	Incorporated the Certificate Renewal, Update, Re-key proposal, the Key Encoding proposal; removed normative words "must", "shall", "required", "will", and "can"; added Create Key Pair example; updated the references and acronyms list; incorporated comments from RobertH and SubhashS; updated the Authentication section; added minor edits and clarifications.
draft-02	2009-10-09	Indra Fitzgerald	Incorporated Rod Wideman's comments on the language. Changed the heading indentation, paragraph style, and list styles according to the OASIS template guidelines. Added additional references. Replaced the TBDs. Added a use-case for registering a wrapped key as an opaque cryptographic object.
draft-03	2009-10-21	Indra Fitzgerald	Added the list of participants to Appendix B. Clarified the Authentication section (section 3.1) and added examples. Modified the title page. Performed minor editorial changes.
draft-04	2009-11-06	Indra Fitzgerald	Incorporated Elaine's comments. This is the tentative revision for public review.
draft-05	2009-11-09	Indra Fitzgerald	Minor edits to the reference sections.
draft-06	2010-02-24	Indra Fitzgerald	Addressed public review comments. Clarified how templates work (section 3.6). Added Judy Furlong's proposal on using the same asymmetric key pair in multiple algorithms (section 3.34).
draft-07	2010-03-04	Indra Fitzgerald	Clarified that the Destroy operation cannot destroy Active objects (section 3.5).
draft-08	2010-03-17	Indra Fitzgerald	Added the Server Policy section (2.5). Added the Credential section (3.1.1) to the Authentication section. Replaced SSL/TLS with TLS. Updated the participant list. Other minor edits.
draft-09	2010-03-18	Indra Fitzgerald	Renamed Role Type to Key Role Type. Updated the participant list.
