Technical Committee:

OASIS Security Services TC

Chair(s):

Hal Lockhart, BEA Systems, Inc.
Brian Campbell, Ping Identity Corporation

Editors:

Scott Cantor, Internet2

Abstract:

This profile describes a set of rules for SAML metadata producers and consumers to follow such that federated relationships can be interoperably provisioned, and controlled at runtime in a secure, understandable, and self-contained fashion.

Status

This document was last revised or approved by the SSTC on the above date. The level of approval is also listed above. Check the current location noted above for possible later revisions of this document. This document is updated periodically on no particular schedule.

34 TC members should send comments on this specification to the TC's email list. Others
35 should send comments to the TC by using the "Send A Comment" button on the TC's
36 web page at <http://www.oasis-open.org/committees/security>.
37 For information on whether any patents have been disclosed that may be essential to
38 implementing this specification, and any offers of patent licensing terms, please refer to the IPR
39 section of the TC web page (<http://www.oasis-open.org/committees/security/ipr.php>).
40 The non-normative errata page for this specification is located at [http://www.oasis-
open.org/committees/security](http://www.oasis-
41 open.org/committees/security).

42 Notices

43 Copyright © OASIS Open 2009. All Rights Reserved.

44 All capitalized terms in the following text have the meanings assigned to them in the OASIS Intellectual
45 Property Rights Policy (the "OASIS IPR Policy"). The full Policy may be found at the OASIS website.

46 This document and translations of it may be copied and furnished to others, and derivative works that
47 comment on or otherwise explain it or assist in its implementation may be prepared, copied, published,
48 and distributed, in whole or in part, without restriction of any kind, provided that the above copyright notice
49 and this section are included on all such copies and derivative works. However, this document itself may
50 not be modified in any way, including by removing the copyright notice or references to OASIS, except as
51 needed for the purpose of developing any document or deliverable produced by an OASIS Technical
52 Committee (in which case the rules applicable to copyrights, as set forth in the OASIS IPR Policy, must be
53 followed) or as required to translate it into languages other than English.

54 The limited permissions granted above are perpetual and will not be revoked by OASIS or its successors
55 or assigns.

56 This document and the information contained herein is provided on an "AS IS" basis and OASIS
57 DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO ANY
58 WARRANTY THAT THE USE OF THE INFORMATION HEREIN WILL NOT INFRINGE ANY
59 OWNERSHIP RIGHTS OR ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A
60 PARTICULAR PURPOSE.

61 OASIS requests that any OASIS Party or any other party that believes it has patent claims that would
62 necessarily be infringed by implementations of this OASIS Committee Specification or OASIS Standard,
63 to notify OASIS TC Administrator and provide an indication of its willingness to grant patent licenses to
64 such patent claims in a manner consistent with the IPR Mode of the OASIS Technical Committee that
65 produced this specification.

66 OASIS invites any party to contact the OASIS TC Administrator if it is aware of a claim of ownership of
67 any patent claims that would necessarily be infringed by implementations of this specification by a patent
68 holder that is not willing to provide a license to such patent claims in a manner consistent with the IPR
69 Mode of the OASIS Technical Committee that produced this specification. OASIS may include such
70 claims on its website, but disclaims any obligation to do so.

71 OASIS takes no position regarding the validity or scope of any intellectual property or other rights that
72 might be claimed to pertain to the implementation or use of the technology described in this document or
73 the extent to which any license under such rights might or might not be available; neither does it
74 represent that it has made any effort to identify any such rights. Information on OASIS' procedures with
75 respect to rights in any document or deliverable produced by an OASIS Technical Committee can be
76 found on the OASIS website. Copies of claims of rights made available for publication and any
77 assurances of licenses to be made available, or the result of an attempt made to obtain a general license
78 or permission for the use of such proprietary rights by implementers or users of this OASIS Committee
79 Specification or OASIS Standard, can be obtained from the OASIS TC Administrator. OASIS makes no
80 representation that any information or list of intellectual property rights will at any time be complete, or
81 that any claims in such list are, in fact, Essential Claims.

82 The name "OASIS" is a trademark of [OASIS](#), the owner and developer of this specification, and should be
83 used only to refer to the organization and its official outputs. OASIS welcomes reference to, and
84 implementation and use of, specifications, while reserving the right to enforce its marks against
85 misleading uses. Please see <http://www.oasis-open.org/who/trademark.php> for above guidance.

1 Introduction

107

108 The SAML V2.0 metadata specification [SAML2Meta] defines an XML schema and a set of basic
109 processing rules intended to facilitate the implementation and deployment of SAML profiles, and generally
110 any profile or specification involving SAML. Practical experience has shown that the most complex
111 aspects of implementing most SAML profiles, and obtaining interoperability between such
112 implementations, are in the areas of provisioning federated relationships between deployments, and
113 establishing the validity of cryptographic signatures and handshakes. Because the metadata specification
114 was largely intended to solve those exact problems, additional profiling is needed to improve and clarify
115 the use of metadata in addressing those aspects of deployment.

116 This profile is the product of the implementation experience of several SAML solution providers and has
117 been widely deployed and successfully used in furtherance of the goal of scaling deployment beyond
118 small numbers into the hundreds and thousands of sites, without sacrificing security.

119 Experience has shown that the most frustrating part of using SAML (and many similar technologies) is
120 that products approach the use of cryptography and trust in wildly inconsistent ways, and often the
121 libraries that such products depend on do the same in their own domains. Key management is hard, and
122 often relies on complicated tools with cryptic output. Standards only help insofar as they can be
123 understood and widely implemented; this has generally not occurred above a basic level of cryptographic
124 correctness. A formal public key infrastructure (PKI) is a tremendously complex, and some would say
125 intractable, goal; it could be argued that SAML itself is a reaction to this. Often, the security of
126 deployments is based on a presumption that required practices such as certificate revocation checking
127 are being performed, when in fact they are not.

128 Of course, it is the case that some deployments, at least to date, have overcome some or all of these
129 problems. They may have a mature PKI, possibly one that existed long before their use of SAML, or they
130 may require such a PKI for other purposes. In such cases, it is obviously less beneficial to deploy a
131 second trust infrastructure based on SAML metadata. Another factor in this profile's usefulness is the
132 relationship between SAML and the other security technologies involved in a deployment; if the use of
133 SAML is subordinated to a secondary role, this profile may be less applicable.

134 The purpose of this profile is to guarantee that in a correct implementation, all security considerations not
135 deriving from the particular cryptography used (i.e., algorithm strength, key sizes) can be isolated to
136 metadata exchange and acceptance, and not affect the runtime processing of messages. In other words,
137 given a metadata instance and presuming that it is successfully processed and has not been updated or
138 superseded, it must be possible with no other information supplied to determine whether a given
139 credential (e.g., a key or certificate) will be accepted by an implementation when used to secure a SAML
140 protocol or assertion.

141 If an implementation can be shown to rely solely on the acceptance of metadata to derive trust, it can be
142 reasoned about in a much simpler way, and the security exposures can be well understood. Furthermore,
143 this profile accomplishes a number of additional practical goals:

- 144 • simplifying ordinary implementations and deployments
- 145 • reducing the technical foundation required to understand and use implementations
- 146 • scaling the provisioning of federated relationships (via processing of metadata batches)
- 147 • facilitating the use of XML encryption without dependency on weaker methods for establishing
148 knowledge of public keys (e.g., guessing based on TLS server certificates)
- 149 • radically simplifying interactions between existing federated deployments (i.e. interfederation)

150 Most importantly, these goals can be accomplished without sacrificing security. Too often, the reaction to
151 security complexity is to produce competing approaches that start by rejecting the notion that a
152 substantial degree of security is achievable in the general case.

153 Another benefit of this profile is to produce a greater awareness of the importance of securing the
154 exchange of metadata. Deployers have sometimes tended to ignore this issue by falling back on the
155 assumption that the underlying PKI would provide the real security of the system, resulting in other
156 exposures due to insecure provisioning of other important information.

157 Finally, note that, in addition to SAML V2.0 itself, this profile is applicable to any set of use cases
158 supported by SAML metadata, including SAML V1.x profiles (as in [SAML1Meta]) and any other
159 specifications that may profile SAML metadata.

160 1.1 Notation

161 This specification uses normative text.

162 The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD
163 NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this specification are to be interpreted as
164 described in [RFC2119]:

165 ...they MUST only be used where it is actually required for interoperation or to limit behavior
166 which has potential for causing harm (e.g., limiting retransmissions)...

167 These keywords are thus capitalized when used to unambiguously specify requirements over protocol
168 and application features and behavior that affect the interoperability and security of implementations.
169 When these words are not capitalized, they are meant in their natural-language sense.

170 Listings of XML schemas appear like this.

171 Example code listings appear like this.

173 Conventional XML namespace prefixes are used throughout the listings in this specification to stand for
174 their respective namespaces as follows, whether or not a namespace declaration is present in the
175 example:

Prefix	XML Namespace	Comments
saml:	urn:oasis:names:tc:SAML:2.0:assertion	This is the SAML V2.0 assertion namespace defined in the SAML V2.0 core specification [SAML2Core].
md:	urn:oasis:names:tc:SAML:2.0:metadata	This is the SAML V2.0 metadata namespace defined in the SAML V2.0 metadata specification [SAML2Meta].
ds:	http://www.w3.org/2000/09/xmldsig#	This is the XML Signature namespace [XMLSig].
xsd:	http://www.w3.org/2001/XMLSchema	This namespace is defined in the W3C XML Schema specification [Schema1]. In schema listings, this is the default namespace and no prefix is shown.
xsi:	http://www.w3.org/2001/XMLSchema-instance	This is the XML Schema namespace for schema-related markup that appears in XML instances [Schema1].

176 This specification uses the following typographical conventions in text: <SAMLElement>,
177 <ns:ForeignElement>, Attribute, **Datatype**, OtherCode.

216 **2 SAML V2.0 Metadata Interoperability Profile**

217 **2.1 Required Information**

218 **Identification:** `urn:oasis:names:tc:SAML:2.0:profiles:metadata-iop`

219 **Contact information:** security-services-comment@lists.oasis-open.org

220 **Description:** Given below.

221 **Updates:** None.

222 **2.2 Profile Overview**

223 The SAML V2.0 profiles [SAML2Prof] and metadata [SAML2Meta] specifications, and subsequent profiles
224 within OASIS and in other communities (e.g., [SAML1Meta]), describe the use of SAML metadata as a
225 means of describing deployment capabilities and providing partners with information about endpoints,
226 keys, profile support, processing requirements, etc.

227 This profile extends these practices by guaranteeing that a given metadata document will be consistently
228 interpreted by any conforming implementation of higher level profiles. To this end, it requires that
229 metadata be usable as a self-contained vehicle for communicating trust such that a user of a conforming
230 implementation can be guaranteed that any and all rules for processing digital signatures, encrypted
231 XML, and transport layer cryptography (e.g., TLS/SSL [RFC4346]) can be derived from the metadata
232 alone, with no additional trust requirements imposed.

233 This profile requires that all runtime decisions are made solely on the basis of key comparisons, and not
234 on any traditionally certificate-influenced basis. A signed metadata file conforming to this specification is
235 semantically equivalent to an X.509-based public key infrastructure (PKI), hence there is little value in the
236 additional layer of complexity provided by certificate validation as specified in [RFC5280]. Operational
237 experience also shows that managing signed metadata is easier than managing a PKI of the
238 corresponding size and scale.

239 **2.3 Metadata Exchange and Acceptance**

240 This profile does not constrain the method(s) by which metadata is published or acquired, but only its
241 content and interpretation. It is assumed that, subject to the security and deployment requirements of the
242 participants, some means of exchanging metadata exists that results in the "acceptance" of metadata by
243 a consumer. Acceptance in this profile is defined as an explicit treatment of everything in the metadata as
244 "true", for the purposes of the metadata consumer's operational behavior. The truth of a given set of
245 metadata is of course contingent upon the metadata not being superseded by newer metadata, which
246 may conflict with, and therefore render obsolete, the earlier information.

247 In other words, this profile does not define how (or how often) metadata is exchanged or how and why it
248 is trusted, but rather assumes that it is exchanged and trusted, and proceeds from that starting point.
249 Dynamic exchange (as described in [SAML2Meta]), manual exchange, the aggregation and signing of
250 metadata by third parties, or any other mechanism, can be used in conjunction with this profile. Note that
251 verification of metadata signatures, if applicable, is considered to be part of this prerequisite step.

252 The rest of this profile deals with the requirements for producing metadata, and a conformant consumer's
253 obligations having accepted it.

254 Finally, note that accepting metadata does not imply that a relying party will interoperate with a specific
255 asserting party; it implies only that if it does so, it does so in a predictable fashion based on the metadata
256 it accepts about that party.

257 **2.4 Implementation Constraints**

258 **2.4.1 Peer Authentication**

259 An additional constraint is necessitated by the inability of SAML metadata to express the authentication
260 requirements of back-channel communications between SAML-using entities, such as via the SAML
261 SOAP binding [SAML2Bind]. In lieu of extending metadata to capture such requirements, this profile
262 assumes that such communications are secured by means of some combination of TLS/SSL and digital
263 signing. If this assumption cannot be made, this profile might need to be supplemented in such scenarios.

264 **2.5 Metadata Producer Requirements**

265 A producer of metadata that adheres to this profile may be an actual participant in a SAML (or other)
266 profile, or an aggregator of metadata describing many such participants. In either case, the content of the
267 metadata itself is independent of its source and MUST stand alone as a description of the requirements
268 for securely communicating with the entity (or entities) described therein, to the extent that the constructs
269 of the SAML V2.0 metadata specification [SAML2Meta] can express these requirements.

270 Subject to any constraints of the exchange mechanisms in use, a conforming metadata instance may be
271 rooted by either an `<md:EntityDescriptor>` or `<md:EntitiesDescriptor>` element. Any
272 `<md:RoleDescriptor>` element (or any derived element or type) appearing in the metadata instance
273 MUST conform to this profile's requirements.

274 Within the context of a particular role (and the protocols it supports, as expressed in its
275 `protocolSupportEnumeration` attribute), any and all cryptographic keys that are known by the
276 producer to be valid at the time of metadata production MUST appear within that role's element, in the
277 manner described below in section 2.5.1. This includes not only signing and encryption keys, but also any
278 keys used to establish mutual authentication with technologies such as TLS/SSL.

279 Signing or transport authentication keys intended for future use MAY be included as a means of preparing
280 for migration from an older to a newer key (i.e., key rollover). Once an allowable period of time has
281 elapsed (with this period dependent on deployment-specific policies), the older key can be removed,
282 completing the change. Expired keys (those not in use anymore by an entity, for reasons other than
283 compromise) SHOULD be removed once the rollover process to a new key (or keys) has been
284 completed.

285 Compromised keys MUST be removed from an entity's metadata. The metadata producer MUST NOT
286 rely on the metadata consumer utilizing online or offline mechanisms for verifying the validity of a key
287 (e.g., X.509 revocation lists, OCSP, etc.). The exact time by which a compromise is reflected in metadata
288 is left to the requirements of the parties involved, the metadata's validity period (as defined by a
289 `validUntil` or `cacheDuration` attribute), and the exchange mechanism in use.

290 **2.5.1 Key Representation**

291 Each key included in a metadata role MUST be placed within its own `<md:KeyDescriptor>` element,
292 with the appropriate `use` attribute (see section 2.4.1.1 of [SAML2Meta], as revised by E62 in
293 [SAML2Errata]), and expressed using the `<ds:KeyInfo>` element.

294 One or more of the following representations within a `<ds:KeyInfo>` element MUST be present:

- 295 • `<ds:KeyValue>`
- 296 • `<ds:X509Certificate>` (child element of `<ds:X509Data>`)

297 In the case of the latter, only a single certificate is permitted. If both forms are used, then they MUST
298 represent the same key.

299 Any other representation in the form of a `<ds:KeyInfo>` child element (such as `<ds:KeyName>`,
300 `<ds:X509SubjectName>`, `<ds:X509IssuerSerial>`, etc.) MAY appear, but MUST NOT be required
301 in order to identify the key (they are hints only).

302 In the case of an X.509 certificate, there are no requirements as to the content of the certificate apart from
303 the requirement that it contain the appropriate public key. Specifically, the certificate may be expired, not
304 yet valid, carry critical or non-critical extensions or usage flags, and contain any subject or issuer. The use
305 of the certificate structure is merely a matter of notational convenience to communicate a key and has no
306 semantics in this profile apart from that. However, it is RECOMMENDED that certificates be unexpired.

307 2.6 Metadata Consumer Requirements

308 A metadata consumer MUST have the ability to fully provision and configure itself based on the content of
309 a metadata instance that it has accepted (see section 2.3), within the constraints of the information
310 represented by the SAML V2.0 metadata specification [SAML2Meta] and any profiles that make use of it.
311 A consumer need not provision policy that is outside the scope of metadata, but MUST have the ability to
312 interoperate with the entities described by a metadata instance that it accepts, constrained by whatever
313 default policies it applies.

314 Subject to the constraints of the exchange mechanism(s) in use, a metadata consumer MUST be able to
315 process instances rooted with either an `<md:EntityDescriptor>` or `<md:EntitiesDescriptor>`
316 element. When processing an `<md:EntitiesDescriptor>` element, each `<md:EntityDescriptor>`
317 element contained within it MUST be processed in accordance with this profile.

318 2.6.1 Key Processing

319 Each key expressed by a `<md:KeyDescriptor>` element within a particular role MUST be treated as
320 valid when processing messages or assertions in the context of that role. Specifically, any signatures or
321 transport communications (e.g., TLS/SSL sessions) verifiable with a signing key MUST be treated as
322 valid, and any encryption keys found MAY be used to encrypt messages or assertions (or encryption
323 keys) intended for the containing entity.

324 Subsequent to accepting a metadata instance, a consumer MUST NOT apply additional criteria of any
325 kind on the acceptance, or validity, of the keys found within it or their use at runtime. Specifically,
326 consumers SHALL NOT apply any online or offline techniques including, but not limited to, X.509 path
327 validation or revocation lists, OCSP responders, etc.

328 The following key representations within a `<ds:KeyInfo>` element MUST be supported:

- 329 • `<ds:KeyValue>`
- 330 • `<ds:X509Certificate>` (child element of `<ds:X509Data>`)

331 In the case of the former, the key itself is explicitly identified. In the case of the latter, a metadata
332 consumer MUST extract the public key found in the certificate and MUST NOT honor, interpret, or make
333 use of any of the information found in the certificate other than as an aid in identifying the key used
334 (based, for example, on information found at runtime in an XML digital signature's `<ds:KeyInfo>`
335 element or the certificate presented by a transport peer).

336 Upon identifying a candidate key, a signature can be directly evaluated based on whether it is verifiable
337 with the key. Authentication of a transport peer can be evaluated by extracting the key presented by the
338 peer (often in the form of an X.509 certificate) and comparing it by value to the candidate key. This
339 process has the effect of decoupling the certificates that may be present in metadata from those
340 presented at runtime, provided that the public keys are in fact the same.

341 A metadata consumer, when implementing authentication of a transport peer via TLS/SSL, MAY retain the
342 checking of server certificate names (e.g., `subjectAltName` or `Common Name`) in accordance with
343 [RFC2818]. Note that this constrains the certificates that may be used at runtime for TLS/SSL server
344 authentication, but does not affect certificates that might appear in metadata, because the eventual
345 comparison is based solely on the key.

346 **2.7 Security Considerations**

347 A number of important exposures arise from the reliance on metadata alone to control runtime trust
348 decisions.

349 Metadata becomes a critical tool for the revocation of compromised sites and keys, and all of the
350 standard practices in the use of tools like CRLs become relevant to the consumption of metadata. The
351 specification has the mechanisms to address these issues, but they have to be used. Specifically,
352 metadata obtained via an insecure transport should be both signed, and should expire, so that consumers
353 are forced to refresh it often enough to limit the damage from compromised information. Either the
354 `validUntil` or `cacheDuration` attribute may be appropriate to mitigate this threat, depending on the
355 exchange mechanism.

356 In addition, distributing signed metadata without an expiration over an untrusted channel (e.g., posting it
357 on a public web site) creates an exposure. An attacker can corrupt the channel and substitute an old
358 metadata file containing a compromised key and proceed to use that key together with other attacks to
359 impersonate a site. Repeatedly expiring (using a `validUntil` attribute) and reissuing the metadata
360 limits the window of exposure, just as a CRL does. Note that the `cacheDuration` attribute does not
361 prevent this attack.

362 A broad set of concerns arises in the dynamic exchange of metadata self-published by a site. In such
363 cases, it may seem untenable to trust someone to properly identify their own key, and of course it may be.
364 Rather than constraining the acceptance of that key, this profile relies on securing the exchange and
365 acceptance of the metadata. Traditional PKI protections can be applied to that document and/or its
366 exchange, subsequently leveraging that protection to establish trust in the key within the metadata.

367 For example, when using the Well Known Location resolution profile [SAML2Meta], a producer may use
368 an X.509 certificate to sign the metadata. This certificate can be bound to the metadata through its
369 subject or `subjectAltName` (which might contain a SAML entityID). This ensures the appropriate key/name
370 binding for the signature.

371 **3 Conformance**

372 **3.0.1 SAML V2.0 Metadata Interoperability Profile**

373 A metadata producer conforms to this profile if it can produce metadata consistent with the normative text
374 in section 2.5.

375 A metadata consumer conforms to this profile if it can process metadata consistent with the normative text
376 in section 2.6.

377 **Appendix A. Acknowledgements**

378 The editors would like to acknowledge the contributions of the OASIS Security Services Technical
379 Committee, whose voting members at the time of publication were:

- 380 • Rob Philpott, EMC Corporation
- 381 • John Bradley, Individual
- 382 • Jeff Hodges, Individual
- 383 • Scott Cantor, Internet2
- 384 • Nate Klingenstein, Internet2
- 385 • Bob Morgan, Internet2
- 386 • Joni Brennan, Liberty Alliance Project
- 387 • Tom Scavo, National Center for Supercomputing Applications (NCSA)
- 388 • Frederick Hirsch, Nokia Corporation
- 389 • Ari Kermaier, Oracle Corporation
- 390 • Hal Lockhart, Oracle Corporation
- 391 • Brian Campbell, Ping Identity Corporation
- 392 • Anil Saldhana, Red Hat
- 393 • Kent Spaulding, Skyworth TTG Holdings Limited
- 394 • Emily Xu, Sun Microsystems
- 395 • Duane DeCouteau, Veterans Health Administration
- 396 • David Staggs, Veterans Health Administration

397 The editor would also like to acknowledge the following contributors:

- 398 • Walter Hoehn, University of Memphis
- 399 • Chad LaJoie, SWITCH
- 400 • Ian Young, EDINA, University of Edinburgh
