1 Introduction

This document provides a profile for use of the W3C XML-Signature Syntax and Processing Standard in providing authentication and integrity protection for OASIS eXtensible Access Control Markup Language [XACML] schema instances. Sections 9.2.1 Authentication and 9.2.4 Policy integrity in [XACML] describe requirements and considerations for such authentication and integrity protection.

A digital signature is useful for authentication and integrity protection only if the signed information includes a specification of the identity of the signer and a specification of the period during which the signed data object is to be considered valid. XACML itself does not define the format for such information, as XACML is intended to use other standards for functions other than the actual specification and evaluation of access control policies, requests, and responses.

One appropriate format that has been defined elsewhere is [SAML]. A profile for the use of SAML with XACML schema instances is available in [XACML-SAML]. This profile therefore RECOMMENDS use of XACML schema instances in SAML Assertions, Requests, and Responses, which MAY then be digitally signed as specified in the SAML specification.

This profile also notes various canonicalization issues that must be resolved in order for signed documents to be verified by a relying party.

This profile specification assumes that the reader is familiar with the concept of a digital signature, with the W3C XML-Signature Syntax and Processing Standard, and with XACML.

1.1 Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

1.2 Glossary

Data object

Used in this profile to refer to a digital object that is being signed. A data object could be an XACML PolicySet, Policy, Request context, Response context, or any associated schemas. A data object is referenced inside an [XMLDSIG] <Reference> element using a URI as defined by [RFC2396].

1.3 Normative References

1.4 Non-Normative References

None
2 XML Digital Signature profile of XACML

2.1 Use of SAML

This Profile RECOMMENDS use of XACML schema instances embedded in SAML Assertions, Requests, and Responses as described in [XACML-SAML]. Such SAML objects SHALL be digitally signed as described in Section 5: SAML and XML Signature Syntax and Processing of [SAML].

2.2 Canonicalization

In order for a digital signature to be verified by a relying party, the byte stream that was signed MUST be identical to the byte stream that is verified. To ensure this, the XML document being signed MUST be canonicalized. Section 5: SAML and XML Signature Syntax and Processing of [SAML] specifies use of

Exclusive Canonicalization [ExclC14N].

2.2.1 Namespace elements in XACML data objects

Any XACML data object that is to be signed MUST specify all namespace elements used in the data object. If this is not done, then the data object will attract namespace definitions from ancestors of the data object that may differ from one envelope to another.

When [ExclC14N] is used as the canonicalization or transform method, then the namespace of XACML schemas used by elements in an XACML data object MUST be bound to prefixes and included in the InclusiveNamespacesPrefixList parameter to [ExclC14N].

2.2.2 Additional canonicalization considerations

Additional transformations on the XACML data object must usually be performed in order to ensure that the data object signed will match the data object that is verified. Some of these transformations are listed here, but this Profile does not attempt to specify algorithms for performing these.

If an XACML data object includes data elements that may be represented in more than one form (such as (TRUE, FALSE), (1,0), (true,false)), then a Transform method MUST be defined and specified for normalizing those data elements.

This Profile RECOMMENDS applying the following canonicalizations to values of the corresponding datatypes, whether occurring in XML attribute values or in XACML Attributes.

1. Where a canonical representation for an XACML-defined datatype is defined in http://www.w3.org/2001/XMLSchema, then the value of the datatype MUST be put into the canonical form specified in http://www.w3.org/2001/XMLSchema. This includes boolean (“true”, “false”), double, dateTime, time, date, and hexBinary (upper-case).

2. http://www.w3.org/2001/XMLSchema#anyURI - use the canonical form defined in [RFC2396]

3. http://www.w3.org/2001/XMLSchema#base64Binary - remove all line breaks and white space. Remove all characters following the first sequence of “=” characters. The Base64 Transform (identifier: http://www.w3.org/TR/xmldsig-core/#sec-Base64) MAY be useful in performing this canonicalization.

4. [RFC2253]. If any RDN contains multiple attributeTypeAndValue pairs, re-order the AttributeValuePairs in that RDN in ascending order when compared as octet strings (described in Section 11.6 “Set-of components” of [X.690]).

5. urn:oasis:names:tc:xacml:1.0:data-type:rfc822Name - normalize the domain-part of the name to lower case.
6. XPath expression – apply [XPath2Filt] to put the XPath expression into canonical form.

Schema Centric XML Canonicalization Version 1.0 [ScC14N] describes many canonicalization issues for XML documents that should be addressed.

2.3 Signing schemas

The parsing of any XACML data object depends on having an accurate copy of all schemas on which the XACML data object depends. Note that the inclusion of a schema URI in the XACML schema instance attributes does not guarantee that an accurate copy of the schema will be used: an attacker may substitute a bogus schema that contains the correct identifier. Signatures can help protect against substitution or modification of the schemas on which an XACML data object depends. Use of signatures for this purpose are described in this section.

In most cases, a data object signer SHOULD include a <Reference> element for each schema on which the XACML data object depends in the <SignedInfo> element that contains the <Reference> to or including the XACML data object itself.

In some cases, the data object signer knows that all PDPs that will evaluate a given XACML data object will have accurate copies of certain schemas needed to parse the data object, and does not want to force the PDP to verify the message digest for such schemas. In these cases the data object signer MAY omit <Reference> elements for any schema whose verification is not needed.
3 Conformance

In implementation may conform as a producer and/or a consumer of signed policies.

3.1 As a producer of signed policies

An implementation conforms to this specification as a producer if it is able to produce XACML policies with XML digital signatures as specified in section 2 of this document.

3.2 As a consumer of signed policies

An implementation conforms to this specification as a consumer if it is able to consume XACML policies with XML digital signatures as specified in section 2 of this document.
